FEMSTAT® PREFILL

(butoconazole nitrate) VAGINAL CREAM 2%

SYNTEX

SYNTEX LABORATORIES, INC.
PALO ALTO, CA 94304

Committed to the OB/GYN and women's healthcare

FEMSTAT PREFILL
(butoconazole nitrate) VAGINAL CREAM 2%

BRIEF SUMMARY

INDICATIONS: FEMSTAT® (butoconazole nitrate) vaginal cream 2% is indicated for local treatment of vulvovaginal mycotic infections caused by Candida species. Confirm the diagnosis by KOH smears and/or cultures. FEMSTAT can be used with oral contraceptives and antibiotics. It is effective in non-pregnant women and during the second and third trimesters of pregnancy.

CONTRAINDICATIONS: FEMSTAT is contraindicated in patients hypersensitive to any of the ingredients.

PRECAUTIONS: General: If clinical symptoms persist, repeat microbiological tests to rule out other pathogens and confirm the diagnosis. Discontinue drug if sensitization or irritation occurs.

Information for the Patient: Do not discontinue prematurely during menstruation or because of symptomatic relief.

Carcinogenesis: Animal studies have not been done.

Mutagenesis: Mutagenicity studies were negative.

Impairment of Fertility: Animal studies showed no impairment of fertility.

Pregnancy Category C: Adverse effects were noted in animals treated with high oral doses. No studies were done in women during first trimester. Patients in the second or third trimester have shown no adverse effects attributable to the drug.

Nursing Mothers: Use with caution.

Pediatric Use: Safety and efficacy have not been established.

ADVERSE REACTIONS: Vulvar/vaginal burning in 2.3% of patients, vulvar itching in 0.9%, discharge, soreness, swelling, itching of fingers each in 0.2%. Complaints caused 1.6% to discontinue drug.

DOSAGE AND ADMINISTRATION: Non-pregnant Patients: The recommended dose is one applicatorful of cream (approximately 5 grams) intravaginally at bedtime for three days. Treatment can be extended for an additional three days if necessary.

Pregnant Patients (second and third trimesters only): The recommended dose is one applicatorful of cream (approximately 5 grams) intravaginally at bedtime for six days.

CAUTION:
Federal law prohibits dispensing without prescription.

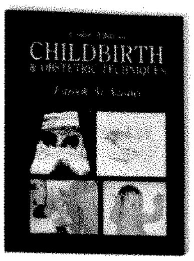
YOUR PATIENTS COUNT ON YOU FOR ANSWERS...

Here are two "must-have" resources to help you explain the mysteries of childbirth to your patients. Using dramatic full-color photos and ultrasound scans, these atlases provide step-by-step coverage of fetal development and childbirth.



New!

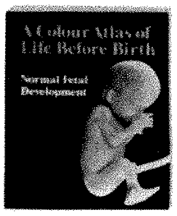
A COLOR ATLAS OF CHILDBIRTH AND OBSTETRIC TECHNIQUES
Farook Al-Azzawi, MBChB, MA, PhD, MRCOG

- Includes coverage of breech delivery, management of twins, operative vaginal delivery and the three most common types of caesarean births.
- Full color photographs depict all aspects of childbirth, with line drawings used to explain movement of the baby.
- Covers prenatal care and management of labor.

1991. 144 pages, 341 ills. A Wolfe Medical Publishers, Ltd. title. (Book Code: 06287)

New!

COLOR ATLAS OF LIFE BEFORE BIRTH: Normal Fetal Development
Marjorie A. England



- Section I covers overall development of the embryo and fetus and their relationship to the placenta, amnion and chorionic sac.
- Section II provides extensive details on the development of individual organ systems.

1990. 216 pages, 716 ills. with 710 in color. A Wolfe Medical Publishers, Ltd. title. (Book Code: 20326)

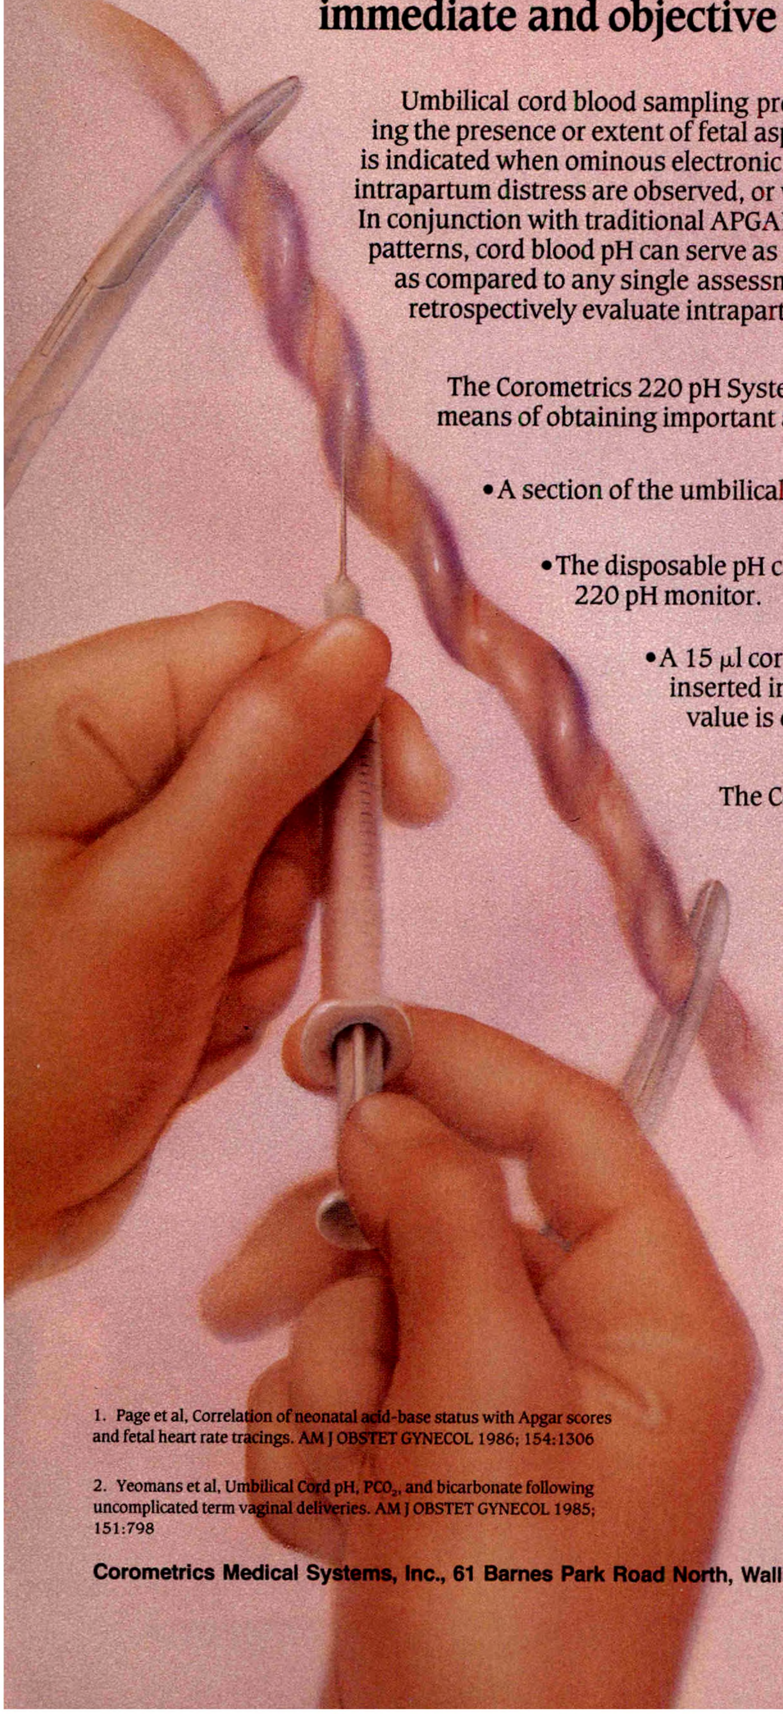
Cord Blood pH...adding objectivity to the newborn assessment.

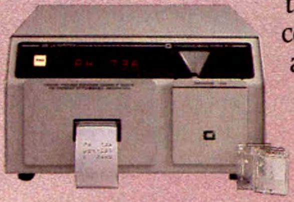
Corometrics 220 pH System provides a simple, immediate and objective means of obtaining cord blood pH.



Umbilical cord blood sampling provides a reliable measurement for objectively determining the presence or extent of fetal asphyxia at delivery. Assessment of cord blood parameters is indicated when ominous electronic fetal heart rate patterns are present, when other signs of intrapartum distress are observed, or when unsuspected neonatal distress is noted at delivery. In conjunction with traditional APGAR scoring methods and the assessment of fetal heart rate patterns, cord blood pH can serve as a more precise indicator of newborn status after delivery as compared to any single assessment method.[1] Cord blood pH values can also be used to retrospectively evaluate intrapartum labor management practices.[2]

The Corometrics 220 pH System is recognized by many to be the simplest, most timely means of obtaining important arterial and venous cord blood pH values.

- A section of the umbilical cord is double-clamped at delivery.
- The disposable pH cartridge is inserted into the 220 pH monitor.
- A 15 μl cord blood sample is collected and inserted into the monitor. The precise pH value is displayed within 15 seconds!



The Corometrics 220 pH System allows for quick and easy on-the-spot assessment of cord pH values. Results are documented with a hard copy printout for the patient chart, pediatrician, or neonatologist.

Umbilical cord blood sampling with the Corometrics 220 pH System . . . the only pH assessment system needed in your delivery room. Call or write us for a system demonstration or a copy of our color procedural guide.

CEFOTAN® IM/IV

(cefotetan disodium)

In intra-abdominal and gynecologic infection due to indicated organisms

For Intravenous or Intramuscular Use
BRIEF SUMMARY

INDICATIONS AND USAGE

TREATMENT: CEFOTAN® (cefotetan disodium) is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary tract infections caused by *E coli*, *Klebsiella* species (including *K pneumoniae*), *Proteus mirabilis* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris, Providencia rettgeri*, and *Morganella morganii*).

Lower respiratory tract infections caused by *Streptococcus pneumoniae* (formerly *D pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K pneumoniae*), and *E coli*.

Skin and skin structure infections caused by *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus pyogenes* and *Streptococcus* species (excluding enterococci), and *E coli*.

Gynecologic infections caused by *Staphylococcus aureus** (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus* species (excluding enterococci), *E coli, Proteus mirabilis, Neisseria gonorrhoeae, Bacteroides* species (excluding *B distasonis, B ovatus, B thetaiotaomicron*), *Fusobacterium* species,* and gram-positive anaerobic cocci (including *Peptococcus* and *Peptostreptococcus* species*).

Intra-abdominal infections caused by *E coli, Klebsiella* species (including *K pneumoniae**), *Streptococcus* species (excluding enterococci), and *Bacteroides* species (excluding *B distasonis, B ovatus, B thetaiotaomicron*).

Bone and joint infections caused by *Staphylococcus aureus*.*

*Efficacy for this organism in this organ system was studied in fewer than ten infections.

Specimens for bacteriological examination should be obtained in order to isolate and identify causative organisms and to determine their susceptibilities to cefotetan. Therapy may be instituted before results of susceptibility studies are known; however, once these results become available, the antibiotic treatment should be adjusted accordingly.

In cases of confirmed or suspected gram-positive or gram-negative sepsis or in patients with other serious infections in which the causative organism has not been identified, it is possible to use CEFOTAN concomitantly with an aminoglycoside. Cefotetan combinations with aminoglycosides have been shown to be synergistic in vitro against many Enterobacteriaceae and also some other gram-negative bacteria. The dosage recommended in the labeling of both antibiotics may be given and depends on the severity of the infection and the patient's condition.

NOTE: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycosidic antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

PROPHYLAXIS: The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (eg, cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

Before therapy with CEFOTAN is instituted, careful inquiry should be made to determine whether the patient has had previous hypersensitivity reactions to cefotetan disodium, cephalosporins, penicillins, or other drugs. This product should be given cautiously to penicillin-sensitive patients. Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs. If an allergic reaction to CEFOTAN occurs, discontinue the drug. Serious acute hypersensitivity reactions may require epinephrine and other emergency measures.

Pseudomembranous colitis has been reported with the use of cephalosporins (and other broad-spectrum antibiotics); therefore, it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use.

Treatment with broad-spectrum antibiotics may alter normal flora of the colon and may permit overgrowth of clostridia. Studies indicate a toxin produced by *Clostridium difficile* is one primary cause of antibiotic-associated colitis. Cholestyramine and colestipol resins have been shown to bind the toxin in vitro.

Mild cases of colitis may respond to drug discontinuance alone. Moderate to severe cases should be managed with fluid, electrolyte, and protein supplementation as indicated. When the colitis is not relieved by drug discontinuance, or when it is severe, oral vancomycin is the treatment of choice for antibiotic-associated pseudomembranous colitis produced by *C difficile*. Other causes should also be considered.

PRECAUTIONS

GENERAL: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity. Those at risk include patients with renal or hepatic impairment or poor nutritional state, the elderly and patients with cancer. Prothrombin times should be monitored in patients at risk and exogenous vitamin K administered as indicated.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

INFORMATION FOR PATIENTS: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc.) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

DRUG INTERACTIONS: Although to date nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

DRUG/LABORATORY TEST INTERACTIONS: A false positive reaction for glucose in urine may occur with Benedict's or Fehling's solution.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels by Jaffe reaction and produce false increases in the levels of creatinine reported.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approximately 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approximately 2-4 times the usual human dose) only 1 of 10 treated animals was affected, and the degree of degeneration was mild.

CEFOTAN® (cefotetan disodium)

Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

USAGE IN PREGNANCY: Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

USAGE IN NURSING MOTHERS: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies, the following adverse effects were considered related to CEFOTAN therapy.

Gastrointestinal symptoms occurred in 1.5% of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700).

Hematologic laboratory abnormalities occurred in 1.4% of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300).

Hepatic enzyme elevations occurred in 1.2% of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2% of patients and included rash (1 in 150) and itching (1 in 700).

Local effects were reported in less than 1.0% of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500). During postmarketing experience with CEFOTAN, anaphylactic reactions and transient thrombocytopenia have been reported.

DOSAGE AND ADMINISTRATION

TREATMENT: The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6* grams	3 g every 12 hours IV

*Maximum daily dosage should not exceed 6 grams.

PROPHYLAXIS: To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION: When renal function is impaired, a reduced dosage schedule must be employed. The following dosage guidelines may be used.

DOSAGE GUIDELINES FOR PATIENTS WITH IMPAIRED RENAL FUNCTION

Creatinine Clearance mL/min	Dose	Frequency
>30	Usual Recommended Dosage*	Every 12 hours
10-30	Usual Recommended Dosage*	Every 24 hours
<10	Usual Recommended Dosage*	Every 48 hours

*Dose determined by the type and severity of infection, and susceptibility of the causative organism.

Alternatively, the dosing interval may remain constant at 12 hour intervals, but the dose reduced to one-half the usual recommended dose for patients with a creatinine clearance of 10-30 mL/min, and one-quarter the usual recommended dose for patients with a creatinine clearance of less than 10 mL/min.

When only serum creatinine levels are available, creatinine clearance may be calculated from the following formula. The serum creatinine level should represent a steady state of renal function.

$$\text{Males:}\quad \frac{\text{Weight (kg)} \times (140 - \text{age})}{72 \times \text{serum creatinine (mg/100 mL)}}$$

$$\text{Females:}\quad 0.9 \times \text{value for males}$$

Cefotetan is dialyzable and it is recommended that for patients undergoing intermittent hemodialysis, one-quarter of the usual recommended dose be given every 24 hours on days between dialysis and one-half the usual recommended dose on the day of dialysis.

HOW SUPPLIED

CEFOTAN is a dry, white to pale yellow powder supplied in vials containing cefotetan disodium equivalent to 1 g and 2 g cefotetan activity for intravenous and intramuscular administration. The 1 g dose is available in 10 mL and 100 mL vials, and the 2 g dose is available in 20 mL and 100 mL vials. CEFOTAN is also available in a pharmacy bulk package of 10 g in 100 mL vials. The vials should not be stored at temperatures above 22°C and should be protected from light.

1 g in 10 mL vial (NDC 0038-0376-10); 2 g in 20 mL vial (NDC 0038-0377-20); 1 g in 100 mL vial (NDC 0038-0376-11); 2 g in 100 mL vial (NDC 0038-0377-21); 10 g in 100 mL vial (NDC 0038-0375-10).

Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women 1491

Abbey B. Berenson, MD, Norma J. Stiglich, MD, Gregg S. Wilkinson, PhD, and Garland D. Anderson, MD
Galveston, Texas

A 20% prevalence of prior physical abuse was found in a pregnant population; physical abuse varied by race and was significantly associated with using drugs, alcohol, and tobacco.

The natural history of HELLP syndrome: Patterns of disease progression and regression 1500

James N. Martin, Jr., MD, Pamela G. Blake, MSN, Kenneth G. Perry, Jr., MD, James F. McCaul, MD, L. Wayne Hess, MD, and Rick W. Martin, MD
Jackson, Mississippi

The patterns of disease progression and regression around delivery are presented for 158 patients with severe preeclampsia-eclampsia and HELLP syndrome.

Suture entrapment and secondary ureteral obstruction 1513

C. Robert Stanhope, MD, Timothy O. Wilson, MD, William J. Utz, MD, Lynwood H. Smith, MD, and Peter C. O'Brien, PhD
Rochester, Minnesota

Postoperative ureteral obstruction can be detected early by small increases in serum creatinine concentration.

Stage IB squamous cell cancer of the cervix: Clinicopathologic features related to survival 1520

Michael P. Hopkins, MD, and George W. Morley, MD
Ann Arbor, Michigan

In stage I squamous cell cancer of the cervix, survival was significantly influenced by tumor grade, size, node status, depth of cervical penetration, and angiolymphatic invasion.

Hysterosalpingography with color Doppler ultrasonography 1530

Albert J. Peters, DO, and Carolyn B. Coulam, MD
Indianapolis, Indiana

Color Doppler flow ultrasonography is used to evaluate tubal patency in an easy, accurate, and cost-effective manner.

Comparison of associated high-risk factors and perinatal outcome between symmetric and asymmetric fetal intrauterine growth retardation 1535

Chin-Chu Lin, MD, Shyr-Jou Su, MD, and L. Philip River, BA
Chicago, Illinois

Except for preeclampsia, no differences were seen in seventeen associated high-risk factors between symmetric and asymmetric IUGR, but the likelihood of preterm birth and neonatal morbidity was higher for symmetric IUGR infants.

TRANSACTIONS OF THE FIFTY-SEVENTH ANNUAL MEETING OF THE PACIFIC COAST OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The issue of animal rights and human rights 1543

James M. Maharry

Whittier, California

Although there are concerted efforts to deny the use of animals in research endeavors, the ultimate goal of biomedical research is to relieve the suffering of both animals and human beings.

Lymphocytic adenohypophysitis: A pituitary mass lesion occurring in pregnancy 1549

Seth L. Feigenbaum, MPH, MD, Mary C. Martin, MD, Charles B. Wilson, MD, and Robert B. Jaffe, MD

San Francisco, California

Pregnant or postpartum women with symptoms of a pituitary mass should be evaluated for lymphocytic adenohypophysitis and corticosteroid therapy considered before routine neurosurgical intervention.

Antibiotic treatment of tuboovarian abscess: Comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens 1556

Susan D. Reed, MD, Daniel V. Landers, MD, and Richard L. Sweet, MD

San Francisco, California

Broad-spectrum β-lactam antibiotics plus doxycycline are as effective as clindamycin-containing regimens in the treatment of tuboovarian abscesses (overall success rate, 75%).

Antepartum testing in the hypertensive patient: When to begin 1563

Richard A. Pircon, MD, David C. Lagrew, MD, Craig V. Towers, MD, Wendy L. Dorchester, MS, Steve E. Gocke, MD, and Roger K. Freeman, MD

Milwaukee, Wisconsin, Orange and Long Beach, California

When to start antepartum fetal surveillance in the hypertensive pregnant patient is presented.

The roles of ultrasonography and amniocentesis in evaluation of elevated maternal serum α-fetoprotein 1571

Karen K. Lindfors, MD, David P. Gorczyca, MD, Frederick W. Hanson, MD, Frances R. Tennant, PhD, John P. McGahan, MD, and Ann G. Peterson, MN

Sacramento, California

Ultrasonography and amniocentesis are complementary in the evaluation of an elevated maternal serum α-fetoprotein level; both are needed for accurate prenatal diagnosis.

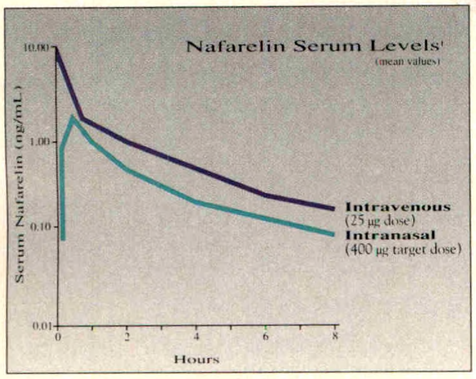
The Only GnRH* Agonist With The Dosing Distinction Of Intranasal Delivery

- Intranasal administration produces nafarelin serum levels comparable to I.V. dosing: In pharmacokinetic studies, SYNAREL was rapidly absorbed into systemic circulation following intranasal administration, with maximum serum concentrations achieved between 10 and 40 minutes.[1]



- B.I.D. controlled-dose intranasal administration suppresses serum estradiol to levels that result in outstanding clinical efficacy, while producing minimal impact on bone and a predictable hypoestrogenic profile.†
- Facilitates ease of patient management should allergic or other adverse events occur.
- Retreatment cannot be recommended since safety data for retreatment are not currently available.

1. Syntex document #829-222-A.

*Gonadotropin-releasing hormone analog.

†There is a small, largely reversible loss in bone density with 6-month treatment. Use of SYNAREL for longer than the recommended 6 months or in the presence of other known risk factors for decreased bone mineral content may cause additional bone loss.

Pregnancy should be ruled out before therapy with SYNAREL is initiated, and patients should be advised to use a non-hormonal method of contraception when taking SYNAREL.

Please see adjacent page for brief summary of prescribing information.

SYNAREL®

(NAFARELIN ACETATE)

NASAL SOLUTION, 2 MG/ML

Setting The Pace In Endometriosis Therapy

BRIEF SUMMARY

SYNAREL® Nasal Solution contains nafarelin acetate (2 mg/mL, expressed as nafarelin base), benzalkonium chloride, glacial acetic acid, sodium hydroxide or hydrochloric acid, sorbitol, and purified water.
INDICATIONS AND USAGE: For management of endometriosis. Experience is limited to women 18 years and older treated for 6 months.
CONTRAINDICATIONS: Hypersensitivity to GnRH, GnRH agonist analogs or any excipients in SYNAREL; undiagnosed abnormal vaginal bleeding; pregnancy or possibility of pregnancy while taking the drug because SYNAREL may cause fetal harm when administered to a pregnant woman. If SYNAREL is used during pregnancy or if the patient becomes pregnant while taking this drug, she should be apprised of the potential hazard to the fetus; use in women who are breast feeding.
WARNINGS: Safe use in pregnancy has not been established clinically. Before starting treatment pregnancy must be excluded.
When used regularly at the recommended dose, SYNAREL usually inhibits ovulation and stops menstruation. Contraception is not insured, particularly if patients miss successive doses. Therefore, patients should use nonhormonal contraception. Advise patients to see their physician if they believe they may be pregnant. If a patient becomes pregnant during treatment, discontinue the drug; apprise patient of the potential risk to the fetus.
PRECAUTIONS Information for Patients: 1. Since menstruation should stop with SYNAREL, the patient should notify her physician if regular menstruation persists. Patients missing successive doses may experience breakthrough bleeding.
2. Patients should not use SYNAREL if pregnant, breast feeding, have undiagnosed abnormal vaginal bleeding, or are allergic to any of its ingredients.
3. Safe use in pregnancy has not been established. Therefore, a nonhormonal method of contraception should be used during treatment. If a patient becomes pregnant during treatment, she should discontinue the drug and consult her physician.
4. Adverse events occurring most frequently in clinical studies are associated with hypoestrogenism. Nasal irritation occurred in about 10% of patients.
5. Induced hypoestrogenic state results in a small loss in bone density over a 6-month treatment course. Some of this loss may not be reversible. During one six-month treatment period, this should not be important. In patients with major risk factors for decreased bone mineral content, i.e., chronic alcohol and/or tobacco use, strong family history of osteoporosis, or chronic use of drugs that can reduce bone mass such as anticonvulsants or corticosteroids, SYNAREL may pose additional risk. In these patients risks and benefits must be weighed carefully. Repeated courses of treatment with GnRH analogs are not advisable in patients with major risk factors for loss of bone mineral content.
6. Patients with intercurrent rhinitis should consult their physician for use of a topical nasal decongestant. If a topical nasal decongestant is required during treatment, it must be used at least 30 minutes after SYNAREL dosing to decrease the possibility of reducing drug absorption.
7. Retreatment cannot be recommended since safety data beyond 6 months are not available.
Drug Interactions: No pharmacokinetic-based drug-drug interaction studies have been conducted. Nafarelin acetate is a peptide primarily degraded by peptidase and not by cytochrome P-450 enzymes, and is only about 80% bound to plasma proteins at 4°C; therefore drug interactions would not be expected to occur.
Drug/Laboratory Test Interactions: SYNAREL in therapeutic doses suppresses the pituitary-gonadal system. Normal function is usually restored 4-8 weeks after treatment is discontinued. Therefore, diagnostic tests of pituitary gonadotropic and gonadal functions during treatment and up to 4-8 weeks after discontinuation of SYNAREL may be misleading.
Carcinogenesis, Mutagenesis, Impairment of Fertility: Carcinogenicity studies were conducted in rats and mice at intramuscular doses up to 110 times and 560 times the maximum recommended human intranasal dose, respectively. These multiples of the human dose are based on the relative bioavailability of the drug by the two routes of administration. As with other GnRH agonists, nafarelin acetate given to laboratory rodents at high doses for prolonged periods induced hyperplasia and/or neoplasia of endocrine organs. At 24 months, there was an increase in the incidence of pituitary tumors (adenoma/carcinoma) in high-dose female rats and a dose-related increase in male rats. There was an increase in pancreatic islet cell adenomas in both sexes, and in benign testicular and ovarian tumors in the treated groups. There was a dose-related increase in benign adrenal medullary tumors in treated female rats. In mice, there was a dose-related increase in Harderian gland tumors in males and an increase in pituitary adenomas in high-dose females. No metastases of these tumors were observed. It is known that tumorigenicity in rodents is particularly sensitive to hormonal stimulation.

Mutagenicity studies using bacterial, yeast, and mammalian systems provided no evidence of mutagenic potential.

Reproduction studies in male and female rats have shown full reversibility of fertility suppression when treatment was discontinued after continuous administration for up to 6 months.
Pregnancy, Teratogenic Effects: *Pregnancy Category X.* Intramuscular SYNAREL was administered to rats throughout gestation at about 0.5, 2, and 7 times the maximum recommended human intranasal dose based on the relative bioavailability by the two routes of administration. An increase in major fetal abnormalities was seen in 4/80 fetuses at the highest dose. A similar study at the same doses in rats and studies in mice and rabbits at doses up to 600 μg/kg/day and 0.18 μg/kg/day, respectively, failed to demonstrate an increase in fetal abnormalities after administration throughout gestation. In rats and rabbits, there was a dose-related increase in fetal mortality and a decrease in fetal weight with the highest dose.
Nursing Mothers: It is not known whether SYNAREL is excreted in human milk. Because many drugs are excreted in human milk, and because the effects of SYNAREL on lactation and/or the breastfed child have not been determined, SYNAREL should not be used by nursing mothers.
Pediatric Use: Safety and effectiveness in children have not been established.
ADVERSE REACTIONS: The most frequently reported adverse reactions were those related to hypoestrogenism. In controlled studies comparing SYNAREL (400 μg/day) and danazol (600 or 800 mg/day), the following adverse reactions were most frequently reported and thought to be drug-related.
Hypoestrogenic: hot flashes (SYNAREL 90%, danazol 69%), decreased libido (22%, 7%), vaginal dryness (19%, 7%), headaches (19%, 21%), emotional lability (15%, 18%), insomnia (8%, 4%); **Androgenic:** acne (13%, 20%), myalgia (10%, 23%), reduced breast size (10%, 16%), edema (8%, 23%), seborrhea (8%, 17%), weight gain (8%, 28%), hirsutism (2%, 6%), increased libido (1%, 6%); **Local:** nasal irritation (10%, 3%); **Miscellaneous:** depression (2%, 5%), weight loss (1%, 3%).

Less than 1% of patients experienced paresthesia, palpitations, chloasma, maculopapular rash, eye pain, urticaria, asthenia, lactation, breast engorgement, and arthralgia. In clinical trials, immediate hypersensitivity thought to be possibly or probably related to nafarelin occurred in 3 (0.2%) of 1509 healthy subjects or patients.
Changes in Bone Density: After 6 months' treatment vertebral trabecular bone density and total vertebral bone mass, measured by quantitative computed tomography (QCT), decreased by an average of 8.7% and 4.3%, respectively, compared to pretreatment levels. There was partial recovery of bone density post-treatment; the average trabecular bone density and total bone mass were 4.9% and 3.3% less than pretreatment levels, respectively. Total vertebral bone mass, measured by dual photon absorptiometry (DPA), decreased by a mean of 5.9% at end of treatment. Mean total vertebral mass, re-examined by DPA 6 months post-treatment, was 1.4% below pretreatment levels. There was little, if any, decrease in the mineral content in compact bone of the distal radius and second metacarpal. Use for longer than the recommended 6 months or in presence of other known risk factors for decreased bone mineral content may cause additional bone loss.
Changes in Laboratory Values: *Plasma enzymes.* During clinical trials SGOT and SGPT levels were more than twice the upper limit of normal in only one patient each. There was no other evidence of abnormal liver function and levels returned to normal after treatment was stopped.
Lipids. At enrollment and at end of treatment, 9% of patients on SYNAREL 400 μg/day and 2% on danazol had total cholesterol values above 250 mg/dL.

Of those with pretreatment cholesterol values below 250 mg/dL, 6% on SYNAREL and 18% on danazol had post-treatment values above 250 mg/dL.

Mean (±SEM) pretreatment values for total cholesterol from all patients were 191.8 (4.3) mg/dL in the SYNAREL group and 193.1 (4.6) mg/dL in the danazol group. At the end of treatment, mean values from all patients were 204.5 (4.8) mg/dL in the SYNAREL group and 207.7 (5.1) mg/dL in the danazol group. These increases from pretreatment values were significant ($p < 0.05$) in both groups.

Triglycerides were increased above the upper limit of 150 mg/dL in 12% of the patients on SYNAREL and in 7% of the patients on danazol.

At the end of treatment, no patients on SYNAREL had abnormally low HDL cholesterol fractions (< 30 mg/dL) compared with 43% of patients on danazol. No patients on SYNAREL had abnormally high LDL cholesterol fractions (> 190 mg/dL) compared with 15% of those on danazol. There was no increase in the LDL/HDL ratio in patients on SYNAREL, but approximately a 2-fold increase in the LDL/HDL ratio in patients on danazol.
Other changes. In comparative studies, the following changes were seen in approximately 10% to 15% of patients. SYNAREL was associated with elevations of plasma phosphorous and eosinophil counts, and decreases in serum calcium and WBC counts. Danazol therapy was associated with an increase of hematocrit and WBC.
OVERDOSAGE: At present there is no clinical evidence of adverse effects following overdosage of GnRH analogs.

Contents continued from page 10A

Preeclampsia as the great impostor 1577

Robert C. Goodlin, MD

Denver, Colorado

Misdiagnosis of medical or surgical problems such as pregnancy-induced hypertension or HELLP syndrome can be life threatening.

Mechanisms of asphyxial brain damage, and possible pharmacologic interventions, in the fetus 1582

Mauricio I. Espinoza, MD, and Julian T. Parer, MD, PhD

San Francisco, California

Neuronal cell death as a result of asphyxia occurs after a complex series of biochemical reactions, and some of these pathways may be amenable to pharmacologic interruption.

Ovarian response in superovulated cycles after suppression with oral contraceptive steroids 1592

Kenneth A. Burry, MD, Laura H. Greenberg, MD, and Phillip E. Patton, MD

Portland, Oregon

Oral contraceptive steroids can be used to suppress endogenous gonadotropins before in vitro fertilization; the ovaries normally respond to stimulation with clomiphene or human menopause gonadotropin, but there is a high cancellation rate because of dominant follicles or luteinizing hormone surges.

Significance of oligohydramnios complicating pregnancy 1597

Lewis Shenker, MD, Kathryn L. Reed, MD, Caroline F. Anderson, RDMS, and Nydia A. Borjon, RDMS

Tucson, Arizona

Eighty pregnancies complicated by oligohydramnios are reviewed and analyzed.

Hormonal inhibition of the endometrium for resectoscopic endometrial ablation 1601

Philip G. Brooks, MD, Scott P. Serden, MD, and Irene Davos, MD

Los Angeles, California

Histologic examination of the endometrium in 25 patients after suppression with progestins, danazol, or leuprolide acetate before resectoscopic endometrial ablation revealed marked differences in thickness, vascularity, and glandular pattern, with progestins producing the poorest inhibition and leuprolide acetate the best; in addition, the depth of thermal damage was the greatest in progestin-prepared endometria and least for leuprolide-prepared cases.

Vulvar vestibulitis: Prevalence and historic features in a general gynecologic practice population 1609

Martha F. Goetsch, MD

Portland, Oregon

A cross-sectional study of vestibular sensitivity revealed a high prevalence of complaints and two major subsets of patients.

(Contents continued on page 14A)

Contents continued from page 13A

Gliomatosis peritonei with malignant transformation: A case report and review of the literature 1617
Gerald Shefren, MD, John Collin, MD, and Olive Soriero, MD, PhD
Mountain View, California

Malignant transformation of previous mature glial implants was observed in a patient with a grade 3 immature teratoma of the ovary.

The use of potassium-titanyl-phosphate laser for laparoscopic removal of ovarian endometrioma 1622
Richard P. Marrs, MD
Los Angeles, California

Successful use of the KTP laser for laparoscopic removal of an endometrioma is described.

Organ transplantation and pregnancy 1629
E. Paul Kirk, MD
Portland, Oregon

A case of a term pregnancy after a cardiac transplant is described, and a review of the issues surrounding pregnancy and major organ (other than renal) transplantation is conducted.

Transabdominal cervicoisthmic cerclage: A reappraisal 25 years after its introduction 1635
Miles J. Novy, MD
Portland and Beaverton, Oregon

Transabdominal cervicoisthmic cerclage for patients with short, scarred, or deformed cervices resulted in a 90% fetal salvage rate; a simplified technique produced little operative blood loss.

Improved mammographic accuracy 1643
S. Gainer Pillsbury, Jr., MD, John S. Link, MD, and Susan Roux, MD
Long Beach, California

The positive predictive value of screening mammography can be improved by utilizing ancillary imaging procedures to evaluate suspicious findings before recommending biopsy.

Conservative management of breast fibroadenomas 1647
William H. Hindle, MD, and Leopoldo J. Alonzo, BS
Los Angeles, California

Review of 498 excised breast fibroadenomas and 17 phyllodes tumors revealed overlapping wide ranges of patient age and tumor size and no coincident or metastatic malignancies.

Fetal choroid plexus cysts in the second trimester of pregnancy: A cause for concern 1652
Lawrence D. Platt, MD, Dru E. Carlson, MD, Arnold L. Medearis, MD, and Catherine A. Walla, RN, MA, MN
Los Angeles, California

Identification of fetal choroid plexus cysts with or without other ultrasonographically diagnosed abnormalities warrants offering patients genetic counseling and cytogenetic studies.

Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero 1657

Russell K. Laros, Jr., MD, Joseph A. Kitterman, MD, David C. Heilbron, PhD, Ronald M. Cowan, MA, and William H. Tooley, MD

San Francisco, California

Maternal treatment with β-sympathomimetics produced no differences in infant growth and development or in most short-term measures of infant well-being.

Ten-year follow-up of patients with secondary amenorrhea and normal prolactin 1666

Val Davajan, MD, Oscar Kletzky, MD, Michael Vermesh, MD, and Debra J. Anderson, MD

Los Angeles and Torrance, California

We present the prognoses of patients with secondary amenorrhea and their spontaneous recovery of menses and successful conception.

Glucose challenge testing in pregnancy 1673

Duncan R. Neilson, Jr., MD, Richard N. Bolton, MD, Robert P. Prins, MD, and Carl Mark III, MD

Portland, Oregon

Routine glucose challenge testing in a private obstetric practice was costly and did not improve outcome.

Alternative liability insurance: A physician-owned captive insurance company 1680

George F. Lee, MD

San Francisco, California

Captive insurance companies represent a viable alternative to commercial carriers for the provision of medical malpractice insurance.

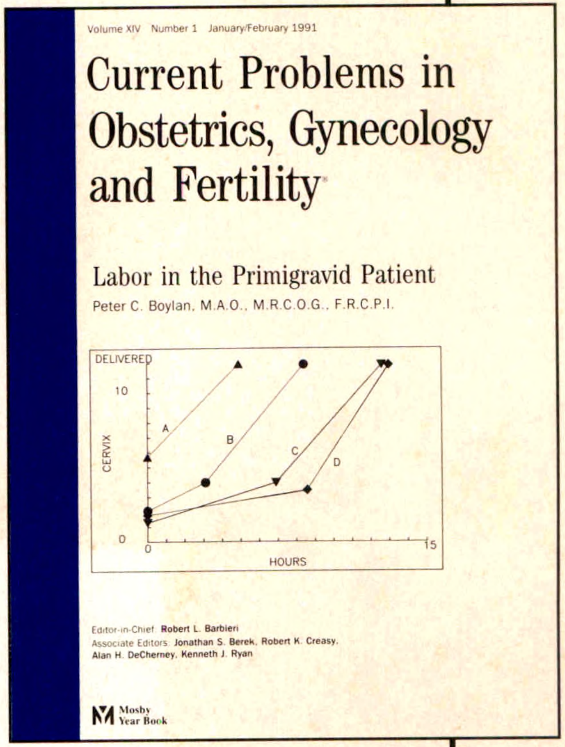
A practical, clinical guide to problems you see in daily practice...

Designed to meet your need for practical information, ***Current Problems in Obstetrics, Gynecology and Fertility*** takes a focused, intensive approach that sets it apart from other periodicals in the specialty.



Volume XIV Number 1 January/February 1991

Current Problems in Obstetrics, Gynecology and Fertility

Labor in the Primigravid Patient

Peter C. Boylan, M.A.O., M.R.C.O.G., F.R.C.P.I.

Editor-in-Chief: Robert L. Barbieri
Associate Editors: Jonathan S. Berek, Robert K. Creasy, Alan H. DeCherney, Kenneth J. Ryan

Mosby Year Book

Every other month, invited experts bring you comprehensive coverage of a **single clinical topic**. Authors address all aspects of the selected topic, including:

- pathophysiology
- non-invasive and invasive diagnosis
- pathology
- drug therapy
- surgical management

In addition, some issues explore the clinical applications of a particular therapeutic or diagnostic modality. Particular emphasis is devoted to the management of fertility and other endocrine problems, as well as high-risk obstetrics.

Current Problems in Obstetrics, Gynecology and Fertility is an outstanding companion to the ob/gyn journals you're currently reading.

Subscribe today, and you'll receive a **free custom binder.** This convenient binder will store 12 issues of your new publication for easy reference. That's a $20 value—yours absolutely free.

Simply complete the postage-paid reply card and return it today. In the U.S., you may call toll-free: 1-800-325-4177, ext. 4351. Outside the U.S., call (314) 872-8370, ext. 4351.

in
Adhesions...

...The GORE-TEX® Surgical Membrane
The Choice in Peritoneal Reconstruction

Successful peritoneal reconstruction requires dependable measures to minimize adhesion reformation following adhesiolysis. The invariant performance of the GORE-TEX Surgical Membrane aids in producing consistent results.

Performance by Design

Composed of the inert biomaterial, expanded polytetrafluoroethylene (e-PTFE), the GORE-TEX Surgical Membrane limits tissue attachment with an extremely small pore size. The nonabsorbable material is a physical barrier which minimizes adhesion between adjacent tissues.

Proven and Established

The GORE-TEX Surgical Membrane has a long record of safety and effectiveness. It has demonstrated reliability among cardiac surgeons for more than 14 years. In addition, recent use in a multi-center clinical study has substantiated safety and shown invariant performance in peritoneal repair.

Convenient

Available in specific configurations tailored for pelvic adhesion reduction, the GORE-TEX Surgical Membrane – *Configured for Peritoneal Reconstruction* is packaged sterile and **can be resterilized.**

Choose the GORE-TEX Surgical Membrane for invariant performance in peritoneal reconstruction. To receive further information or to consult an application specialist, call **800-437-8181**. For orders and overnight delivery 24 hours a day, please call **800-528-8763**.

GORE
Creative Technologies Worldwide

☐ *Please send further information on the GORE-TEX® Surgical Membrane.*
☐ *Please arrange for a free clinical sample.*
☐ *Please have your sales representative call for an appointment.*

INFORMATION FOR AUTHORS

Editorial policies

The requirements for manuscripts submitted to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY conform to the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" established by the International Committee of Medical Journal Editors and published in *Annals of Internal Medicine* 1988;108:258-65. Certain requirements unique to our JOURNAL are provided in Information for Authors, published in each issue of the JOURNAL.

Manuscript submission. Manuscripts should be submitted to one of the two Editors in Chief as follows:

1. **Dr. Zuspan**—manuscripts from the eastern United States and from England, Israel, and Italy, manuscripts written for Clinical Opinion and Current Development, Letters to the Editors, and all manuscripts presented before one of the official sponsoring societies, except the Society for Gynecologic Investigation. *Manuscripts from The Society of Perinatal Obstetricians should be submitted to Dr. Donald R. Coustan, Department of Obstetrics and Gynecology, Women and Infants Hospital of Rhode Island, 101 Dudley St., Providence, RI 02905.*
2. **Dr. Quilligan**—manuscripts from states west of Pennsylvania, West Virginia, Kentucky, Tennessee, and Mississippi; manuscripts from Hawaii, Alaska, Canada, and abroad (except England, Israel, and Italy). Dr. Quilligan is responsible for manuscripts from the Society for Gynecologic Investigation. *Manuscripts from the Society for Gynecologic Investigation should be submitted to Dr. Roger A. Lobo, Women's Hospital, 1240 North Mission Road, Room 1M2, Los Angeles, CA 90033.*

Author's designation of reviewers. When authors submit their manuscripts, they should provide the names and addresses of at least three reviewers for consideration by the Editors.

Copyright statement. The specified copyright statement that follows the Information for Authors in each issue of the JOURNAL must be completed, signed by all authors, and submitted with the manuscript. (The Checklist and Copyright Statement may be torn from the JOURNAL or photocopied for submission.) If not completed in full, it will be returned to the author for completion.

Checklist. The checklist that appears with the copyright statement in each issue of the JOURNAL must be fully completed by the author(s) and sent with each submitted manuscript. A more complete description of each item that must be checked is provided under the appropriate heading in the Information for Authors, which is published in each issue of the JOURNAL. *If the checklist is not completed in full, the deficiencies will be noted, and the form, as well as the manuscript when necessary, will be returned to the author for completion.*

Previous publication. If a report by the same author(s) has been previously published in any medium that deals in any respect whatever with the same patients, same animals, same laboratory experiments, or same data, in part or in full, as those reported in the manuscript being submitted, two reprints of the article or two copies of the manuscript, be it a full-length report or an abstract, must be submitted with the manuscript. The author(s) should inform the Editor of the circumstances, similarities, and differences of the reports. This requirement also applies to the submission of a manuscript in which a few different patients, animals, laboratory experiments, or data were added to those reported in a previous publication or in a submitted or accepted manuscript. Articles previously published in another language will not be considered.

Human and animal experimentation. It is assumed by the Editors that manuscripts emanating from a particular institution are submitted with the approval of the requisite authority. Human experimentation that requires local institutional approval must have this approval *before the ex-*

periment is started and approval must be so indicated in the Methods section of the submitted manuscript. Reports of experiments on animals must *state in the Methods section of the manuscript* that the guidelines for the care and use of the animals *approved by the local institution* were followed. The species of nonhuman animals used in an investigation must be named in the title, abstract, and key words of the manuscript.

Authorship. For manuscripts with two or more authors, each author must qualify by having participated actively and sufficiently in the study that is being performed and reported. The inclusion of each author in the authorship list of a report is based only (1) on substantial contributions to (a) concept and design, or analysis and interpretation of data and (b) drafting the manuscript or revising it critically for important intellectual content; and (2) on final approval by each author of the version of the manuscript. Conditions 1 (a and b) and 2 must both be met. Others contributing to the work should be recognized separately in an Acknowledgment. In the covering letter that accompanies the submitted manuscript, it must be confirmed that all authors fulfilled both conditions.

Conflict of interest. Authors are expected to inform the Editor, in a letter accompanying the submitted manuscript, of any commercial association that might pose a conflict of interest, such as ownership, stock holdings, equity interests and consultant activities, or patent-licensing situations. Such information is confidential, is not given to the consultants, and does not play a part in the decision of the quality or timeliness of the manuscript. If the manuscript is accepted, the author and the Editor will determine how best to release the information. The usual and customary listing of sources of support and institutional affiliations on the title page is proper and does not imply a conflict of interest; only where there is a possible conflict of interest is the author(s) expected to inform the Editor.

Disclaimer. Statements and opinions expressed in articles and communications herein are those of the author(s) and not necessarily those of the Editor(s) or Publisher, and the Editor(s) and Publisher disclaim any responsibility or liability for such material. Neither the Editor(s) nor the Publisher guarantees, warrants, or endorses any product or service advertised in this publication, nor do they guarantee any claim made by the manufacturer of such product or service.

General requirements for preparation of manuscripts

The original and two good-quality photocopies of the manuscript and three sets of glossy prints of illustrations are required.

Manuscripts must be typed double-spaced on one side only of 22 × 28 cm (8½ × 11 inch) white bond paper with 1-inch margins at top, bottom, and sides. Number pages consecutively in the upper right-hand corner in the following order: title page, condensation, abstract, body of text, acknowledgments, references, figure legends, and tables.

Title page. The title page (page 1) should contain in sequence the title (concise and suitable for indexing purposes); author line with first name, middle initial, and last name of each author and each author's highest academic degree (both MD and PhD are acceptable, but honors degrees are not permitted); city(ies), state(s) in which the study was conducted; divisional, or departmental, and institutional affiliations at the time the study was performed; source(s) of financial support; presented line, if applicable; disclaimers, if any; name, address, business and home telephone numbers, and fax number of author to whom requests for reprints should be addressed (if reprints will not be available, it should be so stated); and name, address, business and home telephone numbers, and fax number of author responsible for correspondence concerning the manuscript if different from author to whom reprint requests are addressed. At the bottom of the title page supply a short title for the running head not exceeding 52 characters (including word spaces).

Condensation. On page 2 of the manuscript provide a brief, concise condensation, typed double-spaced, that will appear with the title in publication of the Contents pages of the JOURNAL. It should be a single-spaced sentence, limited to a maximum of 25 words, delineating the essential point(s) made in the manuscript.

Abstract page and key words/phrases. On manuscript page 3, type the abstract, double-spaced, with the required margins and headed by the title of the article and name(s) of author(s). Abstracts for regular articles, Current Investigation, Clinical Opinion, and Current Development may not exceed 150 words. Abstracts for case reports and brief communications may not exceed 50 words. Below the abstract list 3 to 5 *key words* or short phrases for indexing purposes.

Text. Do not hesitate to write your manuscript in the first-person, active voice if it is more appropriate to the information you wish to convey. The passive voice is generally more effective for describing techniques or observations, since the emphasis is on the "action" rather than on the person performing the action.

Only standard abbreviations are to be used. Consult the *Council of Biology Editors Style Manual* or the AMA's *Manual for Authors and Editors.* Abbreviations in the title are not acceptable. They should be avoided, if possible, in the abstract. In the text they should be kept to a practical minimum. The full term for which an abbreviation stands should precede its first use in the text unless it is a standard unit of measurement.

Either the generic, chemical, or proprietary names of drugs may be used. If the generic or chemical name is used, authors may, if they desire, insert the proprietary name in parentheses after the first mention in the text, with the name of the manufacturer and city and state.

Regular articles are customarily organized into the following sections: an introduction and headings that identify Material and Methods, Results, and Comment. Authors may wish to summarize their findings in a short paragraph at the end of the Comment section. This format may not be appropriate for some types of articles.

In the introduction, state concisely the purpose and rationale for the study and cite only the most pertinent references as background.

In the *Material and Methods* section describe briefly (but in sufficient detail to permit other workers to evaluate and reproduce the results) the plan, patients and/or experimental animals and controls, methods and procedures utilized, and statistical method(s) employed.

In the *Results* section present the detailed findings. Include mentions of all tables and/or figures. Figures and tables should supplement, not duplicate, the text; presentation of data in either one or the other will suffice. Emphasize only your important observations; do not compare

Estimating length of manuscripts

With the exception of Current Development articles, the length of text material (introduction through Comment section) in regular manuscripts accepted for publication normally ranges from 750 to 4200 words (an average of 2000 words). A text of 4200 words or more can seldom be accepted, especially if tables and figures are included. The average manuscript of 2000 words of text with abstract, 3 tables with captions, 2 figures with legends, and references makes a 5.7-page article in the JOURNAL. The 2000 words of text alone makes approximately 8 pages of manuscript typed double-spaced with the required 1-inch margins (approximately 250 words per page). A table or figure that occupies both columns of half a JOURNAL page is equivalent to approximately 500 words in manuscript. Thus, if a greater number of illustrations and tables is used, the length of the text should be adjusted accordingly.

your observations with those of others. Such comparisons and comments are reserved for the Comment section.

In the *Comment* section state the importance and significance of your findings but do not repeat the details given in the Results section. Limit your opinions to those strictly indicated by the facts in your report. Compare your findings with those of others. No new data should be presented in this section.

Acknowledgments. Acknowledge only persons who have made substantive contributions to the study.

References. A reasonable number (25) is allowed, except in case reports and brief communications (limited to 2) and in manuscripts for the Current Development section (for which there is no limit). Number references consecutively in the order in which they are mentioned in the text. Use the format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" (Vancouver style) (Ann Intern Med 1988;108:258-65). Journal titles should conform to abbreviations used in *Cumulated Index Medicus.*

Examples (if six or fewer authors, list all; if seven or more authors, list three then et al.):

JOURNAL: Flamm BL, Dunnett C, Fischermann E, Quilligan EJ. Vaginal delivery following cesarean section: use of oxytocin augmentation and epidural anesthesia with internal tocodynamic and internal fetal monitoring. AM J OBSTET GYNECOL 1984;148:759-63.

BOOKS: Ledger WJ. Dystocia and prolonged labor. In: Wilson JR, Carrington ER, eds. Obstetrics and gynecology. St. Louis: CV Mosby, 1987 vol 8:474-93.

Personal communications and unpublished data, if essential, may be used but not as numbered references. If they are used, they are to be referred to, within parentheses, at the appropriate location in the text. If used, the author(s) must obtain written and signed permission for their use from the individual being quoted. This signed permission must accompany the manuscript when it is submitted to the Editor. Published abstracts can be used as numbered references; however, reference to the complete published article is preferred.

Figures. The term *figure* includes all types of illustrations such as graphs, diagrams, photographs, flow charts, and line drawings. A reasonable number of figures will be reproduced without charge, but special arrangements must be made with the Editors for color figures at an additional charge to the author. The quoted charge is per page of color, and as many as eight color figures can be included on one page.

Figures must be cited consecutively in the text in Arabic numerals and identified with a gummed label on the back of the figure with author(s) name(s), title of article, figure number, and top marked clearly. Consistency in size within the article is strongly preferred. Any special instructions regarding sizing should be clearly noted. Do not use paper clips or mar the surface of figures in any way. Figures will be returned only on request by the author.

For *black-and-white figures,* submit three sets of 3 × 4 inch (minimum) to 5 × 7 inch (maximum) unmounted, glossy prints. All lettering must be done with commercially available paste-on letters (or numbers) or by a professional; typed or freehand lettering is not acceptable. All lettering must be in proportion to the drawing, graph, or photograph. Original drawings, appropriately done in black India ink, roentgenograms, and other material must be submitted as glossy prints with good black-and-white contrast.

For *color figures* submit original transparencies and two sets of unmounted prints on glossy (smooth surface) paper. Polaroid prints are not acceptable. Color transparencies must have a color balance (consistency in lighting and film speed) that is acceptable to the author and Editors before acceptance for publication. Please note that 35 mm transparencies are enlarged to twice their original size. If it is important to deviate from this standard, please so indicate when the material is submitted. The top, first author's last name, and figure number must be indicated on the front of each transparency and the back of each print.

Computer-generated figures must be legible and clearly printed in jet black ink on heavy coated paper with either a glossy or dull finish. Any patterns or shadings must be dark enough for reproduction and must be distinguishable from each other. Lines, symbols, and letters should be both smooth and complete. The legend should not appear on the figure. On the back of each figure the name of the first author and the figure number should be given and the top indicated. Three original individual laser or plotter prints are to be submitted *unmounted* with the manuscript. Laser prints should be full size at 300 dots per inch (DPI) or greater full-page resolution; multiple illustrations on a page cannot be accepted. Dot matrix prints and photographic halftones are not acceptable. *Color figures* are acceptable, but special arrangements must be made with the Editors. The colors used must be dark enough and of sufficient contrast for reproduction. With the exception of fluorescent colors, all colors can be reproduced in four-color figures. The preparation and submitting of color prints should fol-

low the preceding guidelines for black-and-white computer-generated illustrations.

Legends to figures. Legends for all figures must be typed double-spaced on paper separate from the text of the manuscript, and these pages must be numbered in sequence after the references. Titles should be included in the legend, not on the print. Original magnifications should be provided. If a figure has been taken from copyrighted material, the legend must give full credit to the original source.

Tables. Tables should be typed on separate sheets of paper, one table to a page, and included at the end of the text. They should be numbered in Roman numerals. Each table must be cited in sequence at an appropriate point in the text. Titles should be brief yet indicate clearly the purpose or content of each table, and each column should be precisely defined by headings. Abbreviations and special designations should be explained in a footnote to the table. If a table or any part thereof has been taken from copyrighted material, a footnote to the table must give full credit to the original source. Special arrangements must be made with the Editors for elaborate tables because of space limitations.

Permissions. Direct quotations, tables, or figures that have appeared in copyrighted material must be accompanied by written permission for their use from the copyright owner and original author along with complete information as to source. Photographs of identifiable persons must be accompanied by signed releases. If not, all recognizable features must be masked.

Requirements for manuscripts

Case reports and brief clinical and basic science communications. Limit of 700 words, 2 references. Include abstract of 50 words maximum, 3 to 5 key words/phrases for indexing purposes, and short title. If tables and/or figures are used, an equivalent number of words must be deducted from the total (see "Estimating Length of Manuscript").

Current Investigation. Same requirements as for regular article.

Clinical Opinion. Limit of 3000 words. Include abstract of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Current Development. Limit of 6000 words. Include abstract of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Letters to the Editors. Letters to the Editors must be submitted in duplicate, typed double-spaced, and the text of the manuscript must be limited to a maximum of 400 words (excluding references, name(s) and address(es) of the signer(s), and the phrase "To the Editors"). The submitted Letter to the Editors must be accompanied by a signed copyright statement. If there are two or more signers of the Letter to the Editors, one of the authors may sign the copyright statement but must add to the statement the following: "I sign for and accept responsibility for releasing this letter on behalf of any and all co-signers." These requirements apply to all types of Letters to the Editors. Letters should be sent to Dr. Zuspan.

Two types of letters will be considered for publication. (1) A Letter to the Editors commenting on an article that has appeared in the JOURNAL should be brief and directly related to the published article. The editorial staff reserves the right to shorten letters if necessary and to make minor editorial alterations without reference to the writer. Letters may be published together with a reply from the original author. If the original author does not respond, a notation indicating "Response declined" will be published. As space for letters is limited, only a selection of letters submitted may be published. (2) A brief case presentation or a short report of a pertinent observation in the form of a Letter to the Editors will be considered for publication.

Announcements. Announcements of major meetings and other significant activities must be received at least 8 weeks before the desired month of publication. All announcements carry a charge of $60 U.S., and the fee must accompany the request to publish. Information will be limited to title of meeting, date, place, and an address to obtain further information. Send announcements and payment, payable to this JOURNAL, to Kay G. Goehler, Senior Manuscript Editor, Journal Editing, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318.

Books. Books received will be listed in the JOURNAL. They should be sent to Dr. Zuspan. No books will be returned.

Reprints

The corresponding author will receive a price schedule and order form at the time of publication. Reprints in quantities must be ordered from the Publisher with the author's consent.

Business communications

Communications of a business nature and all advertising communications should be addressed to: Journal Publisher, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, or call Journal Advertising Production Manager (314) 872-8370.

CHECKLIST AND COPYRIGHT STATEMENT

Both the checklist and the copyright statement forms **must be completed** and sent with each submitted manuscript. If **not** completed, these forms will be returned to the author for completion.

These items appear in each monthly issue of the JOURNAL. A photocopy may be used. An exposition of the requirements given in the checklist is in the Information for Authors, which is published in each issue of the JOURNAL.

CHECKLIST

General

—The original and two copies of the manuscript are submitted.

—The appropriate signed completed checklist and assignment of copyright signed by **all** authors accompany the manuscript.

—Three sets of unmounted glossy prints for regular figures are submitted, properly numbered and labeled on the back of each print.

—Three sets of original computer-generated figures printed on heavy coated paper with either a glossy or dull finish, unmounted, each one on a page, and properly labeled on the back are submitted. None are dot matrix or photographic prints.

—Human experimentation has been approved by the local institution as stated in the Methods section.

—Guidelines for the care and use of animals approved by the institution have been followed as indicated in the Methods section.

—The covering letter with essential information is with the manuscript.

—All elements of the manuscript are typed double-spaced on bond paper with 1-inch margins at top, bottom, and sides.

—All pages are numbered in the following order: title page, condensation, abstract, body of the text, acknowledgments only of persons who have made substantive contributions to the study, references, legends, and tables.

—Signed, written permission from both the copyright holder and the original author for the use of tables, figures, or quotations previously published and their complete references are enclosed with the manuscript.

—Signed, written permission for the use of quotations of personal communications and unpublished data has been obtained from the person(s) being quoted and is enclosed.

Authorship

—In the covering letter that accompanies the submitted manuscript I/we have confirmed that all authors fulfilled both conditions required for authorship.

Conflict of interest

—In the covering letter that accompanies the submitted manuscript the commercial association of the author or of any co-authors that might pose a conflict of interest is described.

Previous publications

—Enclosed with the submitted manuscript are two reprints each of articles the author or co-authors have previously published or have in manuscript form dealing with same patients, same animals, same laboratory experiment, or same data, in part or in full, as those reported in the submitted manuscript. Further explanation is provided in the covering letter that accompanies the submitted manuscript.

—Similarities and differences are identified.

Reviewers

—Names and addresses of three individuals are enclosed.

Title page

—These elements are given in the following sequence, and are typed double-spaced.

—Title.

—Author(s) name(s) and highest academic degree(s) are shown.

—City(ies), state(s), and country other than U.S. in which the study was conducted are given.

—The name(s) of the institution(s) section(s), division(s), department(s) in which the study was performed is provided and the author(s) institutional affiliation at the time of the study is indicated.

—Acknowledgment of financial support is cited.

—Name, address, business and home telephone numbers, and fax number of author to whom requests for reprints are to be sent are included.

—If reprints will not be available, this has been stated on the title page.

—If the corresponding author is different from the author to whom reprint requests are to be sent, his/her name, address, business and home telephone numbers, and fax number have been added.

—At the bottom of the page, a running head not exceeding 52 characters (including word spaces) has been typed.

Condensation

—On a separate sheet of paper, page 2 of the manuscript, a single sentence limited to 25 words delineating the essential point(s) is typed double-spaced.

Abstract

—The abstract is typed double-spaced with required margins (on page 3) headed by the title and the author(s) name, not exceeding 150 words. For case reports and brief communications the limit of 50 words is not exceeded.

—Three to five key words or short phrases are placed beneath the abstract on page 3.

Tables

- Each table headed by a title and numbered in Roman numerals is typed double-spaced on a separate page.
- Tables are cited in sequence in the text.

Figures

- Each is numbered with an Arabic numeral and cited in numerical sequence in the text.
- Original transparencies of **color photographs** appropriately numbered and identified are submitted along with two sets of unmounted prints on glossy paper, numbered and identified on the back.

References

- Are typed double-spaced.
- Are numbered consecutively in the order they are cited in the text.
- The format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" is used. Examples shown in Information for Authors were followed.
- Personal communications and unpublished observations are not used as numbered references but are mentioned in the text with the written approval of the person being quoted. The signed approval is enclosed.

AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

COPYRIGHT STATEMENT

Must be signed by ALL authors

"The undersigned author(s) transfers all copyright ownership of the manuscript entitled

to Mosby–Year Book, Inc., in the event the work is published. The undersigned author(s) warrants that the article is original; is not under consideration by another publication; and its essential substance, tables, or figures have not been previously published. This restriction does not apply to abstracts or press reports published in connection with scientific meetings. The author(s) confirms the final manuscript has been read and each author's contribution has been approved by the appropriate author."

The responsible author(s) must be named____________________ ____________________
(Type name) Signature

Each author's name must be typed underneath the signature.

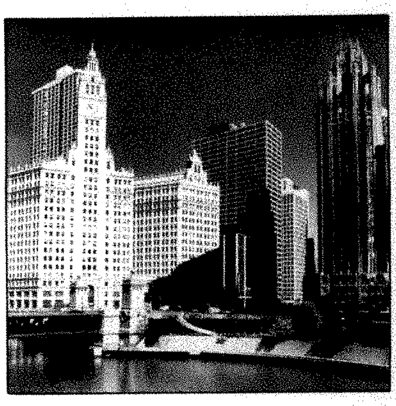
Date: ____________________

CME for the Obstetrician/Gynecologist

• Chicago •



Gynecologic Surgical Techniques, August 22 – 24, 1991
Update your knowledge; refine your surgical skills. Program includes lectures on preoperative evaluation, infections, intraoperative complications, tubal surgery, and more. Videotape and classroom demonstrations on abdominal surgery, vaginal surgery, stress incontinence.

Specialty Review in Obstetrics and Gynecology: Practical Aspects, October 27 – November 2, 1991
A review opportunity for residents and experienced practitioners alike. Program includes a review of case lists (where you can ask faculty experts about your recent cases of special interest) and an optional microscopic slide review.

High-Risk Obstetrics, March 12 – 14, 1992
Designed to help you manage difficult pregnancies more effectively. Covers recent developments in intrauterine growth retardation, genetic counseling, and ultrasound. Also includes discussions on such controversial topics as midforceps and breech deliveries.

CURRENT PROBLEMS IN OBSTETRICS, GYNECOLOGY AND FERTILITY

Editor-in-Chief: **Robert L. Barbieri, MD**
State University of New York at Stony Brook

Current Problems in Obstetrics, Gynecology and Fertility brings you the authoritative, practical information you need to stay current in your specialty and to provide the best possible care to patients.

- Each bimonthly issue provides in-depth, monograph-length coverage (40-60 pages) of a clinical topic of vital interest to practitioners today.
- Topics are selected for relevance to your daily practice: preconceptual counseling, infertility, endocrine problems, high-risk obstetrics, diagnosis and treatment of primary and secondary amenorrhea, pediatric and adolescent gynecology, and more.
- Authors are selected for their expertise; you'll benefit from their balanced perspective on the topic and their wealth of clinical experience.
- Each article is extensively referenced, saving you hours of library research and serving as a long-term, practical resource.

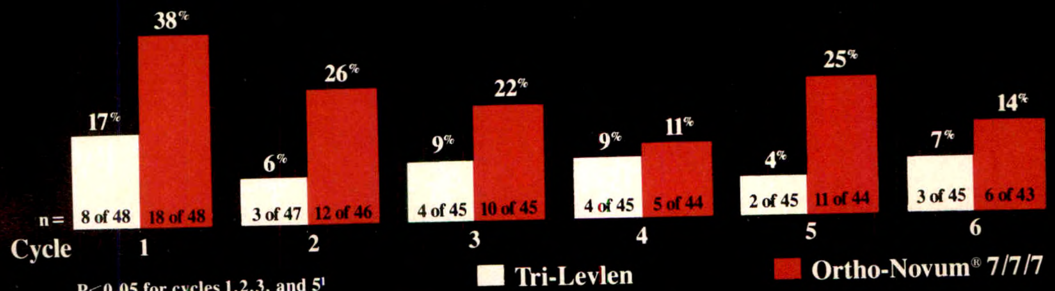
Tri-Levlen® means a low incidence of breakthrough bleeding/spotting*†

Multicenter study demonstrates significantly less breakthrough bleeding/spotting through the first six cycles[1]



$P<0.05$ for cycles 1,2,3, and 5[1]

n = number of women with a bleeding event occurring during a cycle.

TRI·LEVLEN®

Levonorgestrel and ethinyl estradiol tablets—Triphasic regimen

may mean a lot to a woman

---

* Incidence defined as percentage of women with a bleeding event occurring at least once during a pill cycle. Serious as well as minor side effects have been reported with the use of oral contraceptives. The physician should remain alert to the earliest symptoms of serious disease and discontinue oral contraceptive therapy when appropriate. Please see full prescribing information, a brief summary of which follows.

† Defined as intermenstrual bleeding.

Ortho-Novum® is a registered trademark of Ortho Pharmaceutical Corp.

BERLEX Dedicated to innovation in OB/GYN medicine

TRI·LEVLEN® Levonorgestrel and ethinyl estradiol tablets—Triphasic regimen

TRI-LEVLEN® 28 TRI-LEVLEN® 21

BRIEF SUMMARY

Tri-Levlen®—6 brown tablets, each containing 0.050 mg of levonorgestrel (d(-)-13 beta-ethyl-17-alpha-ethinyl-17-beta-hydroxygon-4-en-3-one), a totally synthetic progestogen, and 0.030 mg of ethinyl estradiol (19-nor-17α-pregna-1,3,5(10)-trien-20-yne-3, 17-diol); 5 white tablets, each containing 0.075 mg levonorgestrel and 0.040 mg ethinyl estradiol; 10 light-yellow tablets, each containing 0.125 mg levonorgestrel and 0.030 mg ethinyl estradiol (7 light-green tablets containing inert ingredients are included in the 28-day triphasic regimen).

Indications and Usage

Oral contraceptives are indicated for the prevention of pregnancy in women who elect to use this product as a method of contraception.

Contraindications

Oral contraceptives should not be used in women with any of the following conditions: thrombophlebitis or thromboembolic disorders, a past history of deep-vein thrombophlebitis or thromboembolic disorders, cerebral-vascular or coronary-artery disease, known or suspected carcinoma of the breast, carcinoma of the endometrium or other known or suspected estrogen-dependant neoplasia, undiagnosed abnormal genital bleeding, cholestatic jaundice of pregnancy or jaundice with prior pill use, hepatic adenomas or carcinomas, known or suspected pregnancy.

Warnings

Cigarette smoking increases the risk of serious cardiovascular side effects from oral-contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, gallbladder disease, and hypertension, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemics, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this package insert is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long-term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this labeling, epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of disease, namely, a ratio of the incidence of a disease among oral-contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the difference in the incidence of disease between oral-contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods.

1. *Thromboembolic Disorders and Other Vascular Problems*

a. *Myocardial Infarction.* An increased risk of myocardial infarction has been attributed to oral-contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary-artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral-contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral-contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers over the age of 35 and non-smokers over the age of 40 among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in "Warnings"). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors.

b. *Thromboembolism.* An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to nonusers to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep-vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease due to oral contraceptives is not related to length of use and disappears after pill use is stopped. A two-to four-fold increase in relative risk of postoperative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate post partum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four to six weeks after delivery in women who elect not to breast-feed, or a midtrimester pregnancy termination.

c. *Cerebrovascular diseases.* Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and nonusers, for both types of strokes, while smoking interacted to increase the risk for hemorrhagic strokes. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women.

d. *Dose-related risk of vascular disease from oral contraceptives.* A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high-density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high-density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the nature and absolute amount of progestogen used in the contraceptive. The amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral-contraceptive agents should be started on preparations containing less than 50 mcg of estrogen.

e. *Persistence of risk of vascular disease.* There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral-contraceptive formulations containing 50 micrograms or higher of estrogens.

2. *Estimates of Mortality from Contraceptive Use.* One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral-contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is less than that associated with childbirth. The observation of a possible increase in risk of mortality with age for oral-contraceptive users is based on data gathered in the 1970's—but not reported until 1983. However, current clinical practice involves the use of lower estrogen dose formulations combined with careful restriction of oral-contraceptive use to women who do not have the various risk factors listed in this labeling. Because of these changes in practice and, also, because of some limited new data which suggest that the risk of cardiovascular disease with the use of oral contraceptives may now be less than previously observed, the Fertility and Maternal Health Drugs Advisory Committee was asked to review the topic in 1989. The Committee concluded that although cardiovascular-disease risks may be increased with oral-contraceptive use after age 40 in healthy nonsmoking women (even with the newer low-dose formulations), there are greater potential health risks associated with pregnancy in older women and with the alternative surgical and medical procedures which may be necessary if such women do not have access to effective and acceptable means of contraception. Therefore, the Committee recommended that the benefits of oral-contraceptive use by healthy nonsmoking women over 40 may outweigh the possible risks. Of course, older women, as all women who take oral contraceptives, should take the lowest possible dose formulation that is effective.

3. *Carcinoma of the Reproductive Organs.* Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. The overwhelming evidence in the literature suggests that use of oral contraceptives is not associated with an increase in the risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on the risk of breast cancer for at least a decade following long-term use. A few studies have shown a slightly increased relative risk of developing breast cancer, although the methodology of these studies, which included differences in examination of users and nonusers and differences in age at start of use, has been questioned. Some studies suggest that oral-contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. In spite of many studies of the relationship between oral-contraceptive use and breast and cervical cancers, a cause-and-effect relationship has not been established.

4. *Hepatic Neoplasia.* Benign hepatic adenomas are associated with oral-contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral-contraceptive users. However, these cancers are extremely rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral-contraceptive users approaches less than one per million users.

5. *Ocular Lesions.* There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately.

6. *Oral-Contraceptive Use Before or During Early Pregnancy.* Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. Studies also do not suggest a teratogenic effect, particularly insofar as cardiac anomalies and limb-reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing oral-contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral-contraceptive use should be discontinued if pregnancy is confirmed.

7. *Gallbladder Disease.* Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral-contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral-contraceptive formulations containing lower hormonal doses of estrogens and progestogens.

8. *Carbohydrate and Lipid Metabolic Effects.* Oral contraceptives have been shown to cause glucose intolerance in a significant percentage of users. Oral contraceptives containing greater than 75 micrograms of estrogens cause hyperinsulinism, while lower doses of estrogen cause less glucose intolerance. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the nondiabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects, prediabetic and diabetic women should be carefully observed while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see "Warnings" 1a. and 1d.), changes in serum triglycerides and lipoprotein levels have been reported in oral-contraceptive users.

9. *Elevated Blood Pressure.* An increase in blood pressure has been reported in women taking oral contraceptives and this increase is more likely in older oral-contraceptive users and with continued use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing quantities of progestogens. Women with a history of hypertension or hypertension-related diseases, or renal disease should be encouraged to use another method of contraception. If women with hypertension elect to use oral contraceptives, they should be monitored closely, and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension among ever-and never-users.

10. *Headache.* The onset or exacerbation of migraine or development of headache with a new pattern that is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause.

11. *Bleeding Irregularities.* Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. The type and dose of progestogen may be important. Nonhormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding, as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent.

Precautions

1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed, persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. (See "Warnings" 1d.) 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Patients becoming significantly depressed while taking oral contraceptives should stop the medication and use an alternate method of contraception in an attempt to determine whether the symptom is drug related. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine-and liver-function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability. b. Increased thyroid-binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radioimmunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral-contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See "Warnings" section. 10. PREGNANCY. Pregnancy Category X. See "Contraindications" and "Warnings" sections. 11. NURSING MOTHERS. Small amounts of oral-contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child.

Information for the Patient

See Patient Labeling.

Adverse Reactions

An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see "Warnings" section): thrombophlebitis, arterial thromboembolism, pulmonary embolism, myocardial infarction, cerebral hemorrhage, cerebral thrombosis, hypertension, gallbladder disease, hepatic adenomas or benign liver tumors.

There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: mesenteric thrombosis, retinal thrombosis.

The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug related: nausea; vomiting; gastrointestinal symptoms (such as abdominal cramps and bloating); breakthrough bleeding; spotting; change in menstrual flow; amenorrhea; temporary infertility after discontinuation of treatment; edema; melasma which may persist; breast changes: tenderness, enlargement, secretion; change in weight (increase or decrease); change in cervical erosion and secretion; diminution in lactation when given immediately postpartum; cholestatic jaundice; migraine; rash (allergic); mental depression; reduced tolerance to carbohydrates; vaginal candidiasis; change in corneal curvature (steepening); intolerance to contact lenses.

The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: congenital anomalies, premenstrual syndrome, cataracts, optic neuritis, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, hirsutism, loss of scalp hair, erythema multiforme, cerebral-vascular disease with mitral valve prolapse, lupus-like syndromes, erythema nodosum, hemorrhagic eruption, vaginitis, porphyria, impaired renal function, hemolytic uremic syndrome, Budd-Chiari syndrome, acne, changes in libido, colitis, sickle-cell disease.

Overdosage

Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

Noncontraceptive Health Benefits

The following noncontraceptive health benefits related to the use of oral contraceptives are supported by epidemiological studies which largely utilized oral-contraceptive formulations containing doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol.

Effects on menses: increased menstrual cycle regularity, decreased blood loss and decreased incidence of iron-deficiency anemia, decreased incidence of dysmenorrhea.

Effects related to inhibition of ovulation: decreased incidence of functional ovarian cysts, decreased incidence of ectopic pregnancies.

Effects from long-term use: decreased incidence of fibroadenomas and fibrocystic disease of the breast, decreased incidence of acute pelvic inflammatory disease, decreased incidence of endometrial cancer, decreased incidence of ovarian cancer.

Dosage and Administration

To achieve maximum contraceptive effectiveness, TRI-LEVLEN® tablets (Levonorgestrel and Ethinyl Estradiol Tablets—Triphasic Regimen) must be taken exactly as directed and at intervals not exceeding 24 hours.

For full details on dosage and administration see prescribing information in package insert. 60627-0 5/90

TRANSACTIONS OF THE FIFTY-EIGHTH ANNUAL MEETING OF THE CENTRAL ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Winter hath hope of spring*

Presidential address

L. Russell Malinak, MD
Houston, Texas

A harsh winter wind is blowing on American medicine today.

I use this metaphor to describe the relentless and escalating criticism of our medical care delivery system that has been occurring in the press and other media.

Much of the critical rhetoric has been expressed by those recommending a major restructuring of American medical care. As the volume of criticism grows, it is clear that the objective is to direct public opinion toward a centralized, national system for all patients and away from the private practice of medicine.

Virtually every area of medicine has been the subject of these critics' condemnation. With increasing frequency newspaper and magazine articles, television, and other media have projected a poor image of our profession. In many situations the criticism is unfounded or it is based on incomplete information or erroneous assumptions. I would like to explore one such aspect of American medicine.

Perinatal mortality has been the single most visible medical care issue attracting media attention in the United States during the last three decades.[1] Recent statistics rank the United States eighteenth behind the world leader, Japan. For many years the United States has ranked behind other developed nations; this situation has been called a barometer of our nation's health and has stimulated persistent discussion of the need to change our method of health care delivery.[2]

My interest in this problem began because of a personal experience in 1958. As a medical student I observed the death of an 18-year-old primigravid woman and her infant in utero in association with an eclamptic seizure. The seizure had begun while the patient was at home and continued until her death, which occurred shortly after she arrived at Charity Hospital in New Orleans, Louisiana, prior to any opportunity to initiate therapy. Having seen eclamptic patients successfully treated with good outcome for mother and baby, I was very frustrated by the tragic loss of these two young lives. I was even more frustrated to learn that the patient had not received any prenatal care, in spite of living within easy walking distance of Charity Hospital, where prenatal clinics were routinely and frequently held.

The impact of these deaths stimulated me to follow the scientific literature and media reporting on perinatal mortality through the 1960s, 1970s, and 1980s. There have been consistently negative media reports about, and overt criticism of, American medicine during this 30-year span.

A typical example from the 1960s was published in *Look* magazine. Mr. R.H. Berg[3] stated, "The state of our nation's health is bad. We rank far below less affluent countries. In preventing infant deaths, the United States stands tenth."

Such commentary did not escape the interest and political posturing of President Lyndon Johnson and the architects of his "Great Society."[4] They made persistent calls for so-called "socialized medicine," in line with their many other ideas about the remaking of American society.

The frequency and urgency of media statements calling for a major change in our medical care system have increased, as the rank of the United States in perinatal mortality rate has declined compared with rates in other industrialized countries.

Without critical analysis of the complex origins of

From the Department of Obstetrics and Gynecology and the Center for Reproductive Medicine and Surgery, The Methodist Hospital/Baylor College of Medicine.

Presented at the Fifty-eighth Annual Meeting of the Central Association of Obstetricians and Gynecologists, Louisville, Kentucky, October 11-13, 1990.

Reprint requests: L. Russell Malinak, MD, Department of Obstetrics and Gynecology, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030.

From the phrase "not winter these hath hope of spring" in the poem, "The North Wind Came up Yesternight," Robert Bridges (1844-1930).

6/6/28919

our high perinatal mortality rate or, worse, completely ignoring some crucial issues related to the possible origins of this problem, media reports are currently railing at the medical profession and demanding a major overhaul in the way we take care of patients. As usual, politicians have taken the lead in these headlines.

Recent Texas Senator, now United States Congressman Craig Washington declared, "The state of our health care is just plain appalling." Since our country ranks seventeenth in infant mortality, he says, we must conclude that our health care system has to change.[5]

And, in decrying our high infant mortality rate, Reverend Jesse Jackson stated, "Our present system is not a health care system, it is a **sick** care system." He urged adoption of national health insurance.[6]

Recently, additional headlines suggested that our infant death rate represents a major deficiency in our medical care system. Shapiro, in *The San Francisco Examiner,* claimed that United States health is lagging, highlighting our high infant death rate. "Other countries think we're nuts for paying so much, getting so little," he said.[7] Humphrey Taylor, President of the Louis Harris Polling Organization, maintains we have the costliest, most disliked health care anywhere, because "people live longer and infant mortality rates are lower in other countries," among several other complaints.[8]

You may have noticed different rankings quoted in these news stories published at approximately the same time. They are based on data compiled in different years and drawn from different sources; thus some confusion exists. Also, methods of reporting perinatal mortality from different countries have been highly variable over the last three decades. Particularly in the earlier years, but even in recent times, the variations in data gathering or the **lack** of data disallow many commonly made comparisons.

Nevertheless, what is the scope of the problem in America? Currently, there are 40,000 infant deaths and 30,000 stillbirths per year in our country.[9]

A majority of scientific publications before the 1980s, which ranked countries according to perinatal mortality, used crude infant and neonatal mortality rates.[10]

There are problems with these comparisons. Comparisons of crude neonatal mortality rates cannot be used to determine effectiveness of prenatal or neonatal medical care, because of differences in birth weight distributions between countries. This is analogous to comparing crude death rates without standardizing for important variables such as age and sex.[11]

As the United States slipped progressively farther behind the countries of northern Europe in perinatal mortality in the 1970s and 1980s, peer-review publications began examining factors other than crude infant mortality rates. Variables such as socioeconomic status, maternal age, birth order, and, above all, birth weight were evaluated.

From a data base encompassing 1967 to 1978 in Norway, a country internationally recognized for having low infant mortality, Erickson and Bjerkedal[12] in 1982 noted that in industrialized countries most infant deaths occur in the neonatal period, the first month of life. And they, among others, convincingly demonstrated that neonatal mortality is much more powerfully affected by the birth weight of the infant than it is by any other variable.

Thus, rather than comparing crude neonatal death rates between two countries, they compared birth-weight-specific rates and found that babies of the same weight, on average, have lower death rates in the United States than they do in Norway. These results suggest that perinatal medical care is better in the United States than in Norway. This finding was confirmed by the work of Lee,[13] who compared several national neonatal mortality rates, after adjusting them for very low birth weight, and found similar results.

In an editorial, Paneth[14] stressed that infant mortality is closely tied to indices of social disadvantage. To connect this known association with the observations of Erickson and Bjerkedal, he further stressed that the strong association of social class with neonatal mortality is almost entirely due to its effect on the distribution of birth weights in populations. Put simply, "Poor mothers have small babies and small babies are at high risk of early death."[14]

Because of this fact, two components of neonatal and infant mortality rates must be studied: the distribution of birth weights and the mortality at each birth weight. The former reflects socioeconomic circumstances, although genetic differences in birth weight should not be ignored. The latter reflects the quality of medical care.[14]

Support for these concepts came quickly. David and Siegel[15] and McCormick[16] determined that the contribution of social-behavioral factors to the problem of neonatal mortality can be estimated by determining a population's birth-weight distribution.

Confirming the Norway findings in Sweden, Guyer et al.[11] demonstrated that crude death rates were lower in that country than in Massachusetts, but weight-specific neonatal survival rates were actually better in Massachusetts. The clear implication is that perinatal medical care is at least as good in Massachusetts as in Sweden, if not better. I recall no headlines in the popular press about this information.

Infant mortality means dead children; the emotional impact of this image is heartbreaking. There are few, if any, societies where the death of an infant is not thought of as a personal or family tragedy. Thus prevention of deaths in infants should be a societal imperative.[17]

To reduce the number of neonatal deaths in America, we must leave no stone unturned to learn the many origins of this devastating problem.

We must first concentrate on what is now certainly the most important origin of neonatal death—the societal and socioeconomic factors that result in low-birth-weight babies.

The medical and technical aspects of health care of neonates in America are outstanding and are continually improving.

Resnick et al.[18] have estimated the probability of survival of neonates at birth in 16,183 infants treated from 1980 to 1987 in the Perinatal Intensive Care Program of Florida. The survival curves for infants weighing >1500 gm converged to 95% survival. This is a remarkable record, and the likelihood of survival, even among very-low-birth-weight infants, is high, indicating the commendable level of American medical care. These results are second to none in the world.

Of historical interest is that by 1910 it had been established that the death rate among children was high in proportion to the social status of the population. This relationship was early recognized as a prominent feature of neonatal mortality[19]; however, it received little attention in the scientific literature and virtually no reporting in the popular press for many years. It is puzzling that such a basic concept was overlooked or put aside for such a long period of time.

Recent publications[1, 20] have studied the societal and socioeconomic factors that result in low-birth-weight babies; they have documented known factors and have speculated about others.

Five critical influences on the incidence of low birth weight are commonly discussed; these are: (1) adequacy of prenatal care, (2) smoking, (3) drug abuse, (4) infections, and (5) nutrition. Smoking and drug abuse are given prominence because they can be prevented and cessation will have immediate beneficial results for babies. Other influences include low level of education, single marital status, teenage pregnancy, race, and financial problems. Perhaps the work of Berenson et al.[21] presented at this meeting will result in the addition of physical abuse to this list.

The association of inadequate or absent prenatal care with low birth weight and consequent perinatal mortality is among the best-identified predictors of infant death. Too many poor Americans do not receive appropriate prenatal care.

The American College of Obstetricians and Gynecologists has taken a leadership role among United States organizations in an attempt to impress medical and social institutions with the urgent need to rectify this situation. Dr. Richard Schwarz,[22] current President-Elect of the College, in a 1989 editorial entitled, "Infant Mortality and Access to Care," pointed to the unenviable rank (seventeenth) of America among industrialized nations and stressed that financial and cultural barriers to use of prenatal services exist. He quoted studies indicating that removal of barriers will increase use of services. He explored reasons why access to care might be limited among poor patients in our society. To expand access to care, he called for fundamental social change to overcome existing barriers. Such changes might include improved transportation, child care, educational outreach, and improved insurance for the working poor.

His bottom line was most appropriate: "Only with a combination of medical and social effort can the infant mortality rate in America be reduced to a level that our citizens deserve and in which we can take pride."[22]

Perhaps Dr. Schwarz was responding to data from his own institution, King's County Hospital in Brooklyn, New York. From 133 patients delivered during 1981 to 1987, Delke et al.[23] found that maternal-social factors were associated more often than medical causes in avoidable perinatal deaths. In their study two thirds of the antepartum deaths and one third of the neonatal deaths were related to maternal-social causes.

They emphasized that social factors such as failure to utilize existing prenatal services are linked to low socioeconomic status, as are increased exposure to personal risk factors such as smoking and illicit drug use that are strong predictors of perinatal death.[23] Their study pointed out another important issue: Low socioeconomic status not only adversely influences perinatal mortality because of the high incidence of prematurity but also affects babies delivered at term or after term.

Dr. Schwarz's editorial raises a challenging question. Is the term "access to care," at least in some cases, misleading? Could this phrase divert attention away from a possibly more important basic problem such as underutilization of services? What are the factors that deny a patient access to care? The answers to these questions await comprehensive study. Likewise, why had the patient with eclampsia who died at Charity Hospital 32 years ago not presented for prenatal care?

The relation between smoking and low birth weight has been very well established.[24-27, 27A] A prospective study of 30,596 pregnant American women, controlled for maternal age, ethnicity, education, alcohol use, and eight other factors, indicated that preterm births were increased by 20% in women smoking one or more packs of cigarettes per day; the effect was strongest for births occurring before 33 weeks' gestation, where the excess was 60%.[28] Because of the large number of young

American women who smoke, cessation of smoking during pregnancy and reduction in the duration of prepregnancy smoking have a 39% potential to reduce the incidence of low-birth-weight babies.[11, 25]

A particularly onerous aspect of the tobacco industry has been its recent selective advertising in inner-city neighborhoods. Surveys in Baltimore, Detroit, Washington, St. Louis, and Atlanta have found that the vast majority of billboards in minority neighborhoods promote tobacco or alcohol.[29] Tinsley-Williams[30] criticized such billboards as "24-hour pushers."

In addition to targeting minorities, this industry has relentlessly and successfully projected the image of female smokers as glamorous and chic. Further, it portrays the young female smoker as energetic, sophisticated, and mature. The health consequences of cigarette smoking for the unborn have long been documented, and we now see that lung cancer has surpassed breast cancer as the leading cause of death from malignant neoplasia in women. The incidence and severity of benign chronic lung diseases as secondary consequences of cigarette smoking have soared.

Women are smoking more heavily, inhaling more deeply, and starting to smoke earlier than they did 20 years ago. Every day more than 1600 American teenage girls "light up" for the first time, and more girls are smoking than are boys.[31]

Surveys have demonstrated that women are more likely than men to use cigarettes as a means of coping with stress. Certainly this phenomenon has pertinence to inner city populations, probably to a greater degree than any other segment of our population.

Drug abuse, particularly abuse of crack cocaine, is an epidemic that burst on the nation in the 1980s. The effect on newborn babies has been severely deleterious, not only in neonatal mortality but in long-term morbidity in surviving infants.

Of 353 patients studied, Calhoun[32] found that 91 (25.8%) had positive tests for cocaine at the time of delivery. The prematurity rate was 37% in the cocaine-positive mothers versus 2% in cocaine-negative mothers. Two thirds of the infants had cocaine withdrawal.[32] Hunt[33] recently described a 700% increase in 4 years in drug-addicted neonates at Houston's Lyndon B. Johnson Hospital.

A poignant headline appeared in the *Louisville Courier-Journal* just 2 days ago. Under the title, "Hearing the Cries of Crack," Anna Quindlen[34] described the devastating effects of crack cocaine on neonates. Her statement in this article, "The chasm between rich and poor widens in utero," was certainly provocative. In response to this distressing situation, Dr. Mortimer Rosen[35] stated, "It's almost as if a new form of child abuse is arising in our world."

And, finally, acquired immunodeficiency syndrome, the other epidemic of the 1980s in America, is emerging as an infection with tragic consequences for mothers and babies that will have a growing impact on neonatal mortality and morbidity for the foreseeable future.

These problems are not isolated to inner-city America; they are also well recognized as contributing factors in perinatal mortality in Europe. They just happen to be more prevalent in America.

In every European country studied, the World Health Organization[36] found an increase in deaths with a decrease in socioeconomic status. It concluded that the interaction between socioeconomic status and biologic factors influences levels of perinatal mortality.

Dr. Marsden Wagner[37] recently stated the situation succinctly. On the basis of extended observations of health care delivery on both sides of the Atlantic, he states that, "Infant mortality is not a health problem. It is a social problem with health consequences." He emphasized the need for social support for pregnant women and infants. While I disagree with some of the recommendations he made in this article, his statement carries an important message.

Why hasn't this conclusion been emphasized in the popular press? Clearly, the challenge of reducing perinatal mortality in America is not restricted to changing the way medical care is delivered in our country. This is why it is hard to take the simplistic bashing of the medical profession that is aimed at dismantling our system of medical care.

Some intriguing data are available on medical care in Japan. Recall the major difference between Japan and the United States in neonatal mortality. They have been number one, while we have been number eighteen, mainly as an indication of the differences in social-socioeconomic status. Japan has much lower rates of drug abuse, teenage pregnancy, and babies born out of wedlock, and they have strong family support systems. In contrast to the low perinatal mortality in Japan, there is a substantial difference between the United States and Japan in **maternal** mortality rate, which is more a reflection of the adequacy of medical care. In 1975 the maternal mortality rates per 100,000 live births for Japan and the United States were 29 and 13, respectively.[38] This rate persisted in the 1980s—16 in Japan in 1985 versus 8 in the United States in 1983.[39] These figures indicate that medical care rendered to American mothers is significantly better than that care in Japan. Confirmation of this observation comes from Rosen and Fujimori,[40] who demonstrated that in England and Wales maternal mortality is significantly lower than in Japan; they discovered that the only difference among variables studied was availability of anesthesiologists. They speculated that this difference in medical care delivery was principally responsible for the higher maternal mortality in Japan. Thus the Japanese nation is doing better than our society from a social-behavioral standpoint as evidenced by neonatal mortality, but American medical care is better when maternal mortality is considered.

Revisiting the headlines presented at the outset, it is clear that some statements in the press are erroneous. ("In Japan, Canada, and many European countries, people live longer. . . ."[8]) In Japan, new mothers do not live longer.

Returning to another headline, I conclude, as did Representative Washington,[5] that our ***health care system,*** not necessarily our ***medical*** *care system,* must change; the major emphasis must relate to social-socioeconomic change.

What can we as a profession do to rectify this enormous problem of perinatal mortality? An exciting second example of leadership in this area exhibited by the American College of Obstetricians and Gynecologists was the recent presidential address by Dr. Ezra Davidson,[41] entitled, "A Strategy for Reducing Infant Mortality." In stressing that a woman who starts prenatal care in the first trimester has a fivefold better chance of having a living child than a woman who has no prenatal care, he made a clarion call for detailed, nationwide review of factors that are associated with every perinatal death in America. Because of the diversity of our society, the review will be conducted on a local basis, to include those factors unique to geography and local custom. It will focus not only on medical factors but on life-styles and living conditions, on access and utilization. It will hopefully address the relative importance and meaning of access versus underutilization. His words, "We must not medicalize our societal problems," beautifully emphasize the heart of one of my points today. It is incumbent upon all Fellows of the College, and all American physicians rendering perinatal care, to encourage and facilitate this study. For it is only when there is reasonable knowledge of the origin of the problem that appropriate steps can be taken to change the outcome. In addition, the data gained will most likely blunt or eliminate the attacks on so-called deficiencies in our medical care and emphasize to the American people the societal arena in which the principal challenges lie.

On the basis of the information presented today, I find it unlikely that a wholesale change in the medical care system in America will change our rank in perinatal mortality among nations. Instead, a societal change of major magnitude must be implemented, and the willingness of the American people to attack such basic problems must be put into action.

Perhaps some speculation is in order. Why do the northern Europeans and certain other countries have significantly lower perinatal mortality? It has long been postulated that the more or less homogeneous nature of their societies, which have relatively few truly poor people, permits a more uniform application of medical care.

Wallace et al.[20] in 1989 pointed out that Japan, Sweden, and Finland have shared the number one ranking for lowest infant mortality for a decade on a somewhat rotating basis.

The latter two countries have a widespread network of maternal health clinics that are very well attended by their patients. They report that 95% to 99% not only register for health care but register early. Women are monitored for high risk early and continuously. Both countries have an effective system of education of parents before and after delivery.[42] Thus they have a highly motivated, compliant population whose utilization of medical services occurs at a very high rate. Access to care is associated with a national health service supported by very high individual taxes. They have a lower percentage of teenage births, and sex education as a national policy is taught in primary and secondary schools in Sweden and Finland. Family planning education and services are freely available and are used extensively. Social benefits include allowances for all pregnant women, predelivery maternity leave with salary (60 days in Sweden; 30 days in Finland), and postpartum maternity leave with salary for 1 year.

Among other reasons for low infant mortality, the authors state that populations in Sweden and Finland are generally of high socioeconomic status and have a high standard of living, including education and nutrition. Also they have a broad system of social support. **Any** health care delivery system would shine under these circumstances.

The United States has been compared with other nations, none of which have populations as diverse as ours. None have opened their borders or their hospitals to refugees from around the world. I am not apologizing for our less than homogeneous society. In fact, our diverse population, our "melting pot," is associated with the finest system of government yet devised, and we are the culturally and technologically richest country in the world. We have arrived at this point, on the doorstep of the twenty-first century, because of a longstanding tradition of freedom of expression, freedom of choice, and freedom to work hard and reap the rewards of our labor. This has been the American way, and, as applied to medical care for a majority of Americans, freedom to choose a physician or a hospital and freedom for physicians to elect to treat patients has created the finest medical care system in the world.

In light of the material discussed herein, I feel that our medical care delivery system has not failed and is not second-rate because of our rank in perinatal mortality.

Nevertheless, one should not discount the damage done in moulding public opinion by constant media harping of the worst-case possibilities that exist in health care delivery. In addition to media's exaggeration of certain issues, failure to report the true nature of a health care issue diverts public attention away from the core disorder, as in the social origins of American perinatal mortality. Society's ability to deal with the problem is thereby compromised.

The media are not always negative in reporting medical affairs. On Oct. 3, 1990, Ms. Judy Woodruff on the PBS McNeill-Lehrer News Hour did a piece on infant mortality, which focused principally on the problem of low-birth-weight babies of inner city women, with strong emphasis on crack cocaine use during pregnancy as a cause of perinatal mortality and severe postnatal morbidity. Rather than attacking medical care, the focus was on low-birth-weight babies in the General Hospital Neonatal Intensive Care Unit in Washington, D.C., and the reasons why they were there. The image of those suffering babies presented a very powerful message; the media in working together with the medical profession could expand this type of reporting to tremendously benefit American mothers and babies.

Herein lies a hope of spring.

The role of the media in America has become increasingly more important, because the huge potential for disseminating information can shape the actions and habits of people in all walks of life. In no other health care area could a shift from a negative to a positive message be of more importance than in infant mortality.

In fact, an aggressive, positive, hopeful television campaign could be the linchpin of a program to heighten public awareness and stimulate patients to utilize available prenatal and postnatal services or to learn where and how to get the help they and their babies so desperately need. Television may or may not be the best way; in some cases it **might be the only way** for the health care message to reach deep inner-city or distant rural areas of America.

In reflecting on how potent the media have been in projecting the poor image of American medicine, I realized that they might be equally powerful in projecting a positive health care message related to infant mortality. With the proper format varied to appeal to diverse target audiences, with the use of role models appropriate for those targets, with input from concerned obstetricians and pediatricians, as well as other health care providers, and with adequate funding, a compelling message repetitively broadcast would likely save more infants' lives than would any other single societal effort.

With confidence that such an aggressive program has a chance to succeed, I truly feel **the hope of spring.**

I also feel confident in saying that there is not a major reason to radically change our medical care system, certainly not because we have failed in the area of perinatal mortality. It is ironic to see the escalating calls for centralized, nationalized, or socialized medicine at a time in modern history when many socialistic nations are crumbling and are speeding to rearrange their societies toward market principles that are based on freedom of choice and individual productivity, perhaps emulating the American way.

What tradition brought American medicine to preeminence in the world? What must we protect to ensure optimum medical care for neonates and most Americans in the next century? What must we *not* change?

We must not change the doctor-patient relationship that is based on the traditional private practice model. This is the best model for medical care delivery in the United States. Surveys have repeatedly documented that whereas people may be disgruntled with some aspects of health care, they remain consistently satisfied with their private physician.

American patients want freedom of choice, and autonomy, and privacy. They want to have their own physician who can be understanding, caring, and expert. And they want one who will be their friend.

In England, where once there was near-total government medicine, there are now private hospitals, private practice, and private insurance serving about 10% of the population; since 1981 the growth has been steady at 5% per year. In 1983 23% of professionals and 22% of employers and managers had private medical insurance. In spite of his support for the National Health Service, Vayda[13] states there is a general level of anxiety about the ability of the NHS to meet health care needs, which reinforces the appeal of private alternatives.

It is likely that a pluralistic system will evolve in America. There will be a continued responsibility of local, regional, and federal governments to provide health care for those who **cannot,** or prefer not to, seek private medical care. Also the federal government will continue to be involved with the Veterans Administration system, Public Health Service, Armed Services, etc. A logical area of extension of the federal government would be to provide insurance for all pregnant women and their infants who cannot provide their own means. This would eliminate the lack of prenatal care for purely financial reasons. Would it not be wonderful if such a system permitted establishing a physician-patient relationship for our clinic patients, without major intrusion by the government? You know what that would do for utilization.

For many poor Americans without hope, such a program might also be a **hope of spring.**

Many of us, and likely a majority of the membership of this association, will continue to practice one-on-one medicine on patients who have sought us out, will pay us, and whom we will willingly and proudly serve during the remainder of our professional lifetimes. They will come to us because we have developed an individual style or an area of expertise, because we are caring and competent physicians who are willing and happy to work long hours to serve their needs.

There will be ever-growing numbers of patients who will be involved with one plan or another who will seek health care in a less personalized setting delivered by physicians who will have less interest in the patient as a person and who will function more in the 9-to-5 mode.

But there will remain a substantial number of American patients who will pursue a private doctor-patient relationship, who will remain friends with their physician, and who will solve their health care problems in the American way—they paid for it because they worked for it, because they earned it.

In spite of all the depressing rhetoric, the criticism I call the "bleak winter of our profession," there are many physicians whose voices have been unheard. These are people who have not been interviewed; thus they are not in the statistics. Included among these are many who do not complain about how life, circumstances, and bureaucrats have wronged them. They do not complain because they are too busy—busy carrying out the day-to-day problem-solving and challenges of the practice of medicine, with its usual triumphs, occasional heartbreaks, but always fascinating interactions with patients, colleagues, and allied health professionals.

From my viewpoint, I still have to "pinch myself" to realize that I have been living a lifelong dream to be a physician—and I find it hard to believe that I get paid well to do work that gives me pleasure and satisfaction.

I still see young physicians and students who have that attitude. They are committed students who will one day be fine physicians. They are willing to hang onto a dream; whereas it was easy for you and me to pursue our dream, these students are bombarded with negativity regarding their dream. Perhaps those who persist and establish that precious patient-physician relationship will cherish what they have earned even more than we have.

Therein lies the **hope of spring**—the continuation of this attitude into the next century, so that the practice of medicine in America will remain strong and continue to attract bright individuals on whom the health of this nation will depend.

This **hope of spring** is also embodied in those of us who have learned and practiced and taught in the greatest system of health care delivery this planet has ever known. Continuation of the heart of this system, the private practice of medicine, is dependent on our hard, honest work, our example, and our counsel to the young people around us.

I wish to thank Mrs. Billie Ann Uralinak for her assistance in the preparation of this address.

The mammary stimulation test—A predictor of preterm delivery?

Robert D. Eden, MD, Robert J. Sokol, MD, Yoram Sorokin, MD,
Helen J. Cook, RNC, MSN, Gail Sheeran, RNC, and Lawrence Chik, PhD
Detroit, Michigan

Clinical risk identification for preterm delivery, the major cause of perinatal morbidity and mortality, remains problematic. To test the hypothesis that a provocative test for uterine contractility at the beginning of the third trimester would reliably identify patients destined to be delivered before and at term, we designed the mammary stimulation test. Uterine contractions in response to nipple stimulation at a mean of 28.6 weeks' gestation, were evaluated in 94 gravid patients at risk for preterm delivery. The mammary stimulation test, the results of which were not used for clinical management, was positive in 50% of patients tested and had a sensitivity of 84% and a positive predictive value of 34% ($\chi^2 = 11.15$, $p < 0.01$). Ninety-four percent of patients predicted to be delivered at term actually were delivered at term (negative predictive value). Furthermore, no patients with a negative mammary stimulation test were delivered within 1 month of testing or were delivered of infants weighing <2000 gm. Discriminant analysis indicated that the mammary stimulation test provided information beyond that available from clinical risk factors alone. A cost analysis suggested that the use of the mammary stimulation test could reduce the cost of ambulatory uterine activity monitoring by nearly 50%. If these findings can be validated in additional samples, the mammary stimulation test may be useful in prematurity prevention programs. (AM J OBSTET GYNECOL 1991;164:1409-19.)

Key words: Mammary stimulation test, prematurity, nipple stimulation

Preterm birth remains the major cause of perinatal morbidity and mortality and results in significant expenditures of health care resources.[1,2] Preventing prematurity is highly desirable but is hampered by the limitations of clinical risk assessment. Current programs, including clinical risk assessment, patient behavioral modification, ambulatory uterine activity monitoring, and tocolysis, have not produced a decrease in the incidence of prematurity.[1,3,4]

Clinical risk assessment and scoring for preterm delivery are based primarily on epidemiologic and medical factors, including selected social and demographic factors, obstetric and medical histories, and current pregnancy complications.[5-7] Although risk scoring systems are helpful in identifying women destined to be delivered prematurely, they have low sensitivities and positive predictive values.[6] The addition of ambulatory uterine activity monitoring may contribute to improved identification of the at-risk patient,[8-11] but its cost-effectiveness is questionable.[4,12-16]

Our hypothesis, which is based on a theoretical consideration of the endocrine control of parturition, states that a provocative test of uterine contractility at the beginning of the third trimester could identify patients destined to be delivered prematurely. We designed the mammary stimulation test for this purpose. This study prospectively evaluates the ability of the mammary stimulation test to predict preterm delivery in a sample of at-risk patients.

Methods

During a 6-month period, 94 gravid patients who were between 24 and 32 weeks' gestation and were attending a core-city antenatal clinic for the medically indigent were enrolled in a research protocol approved by the Human Investigation Committee of Wayne State University. Demographic factors, gestational duration, and clinical risk factors were recorded. After written informed consent was obtained, the patient was placed in semi-fowler's position. Doppler fetal heart rate was obtained, and a tokotransducer was applied (Hewlett-

Packard 8040A). According to a standard protocol of nipple stimulation contraction stress testing,[17] baseline uterine activity was evaluated for at least 10 minutes, after which the patient lightly stimulated one breast (nipple) through her clothing for 2 minutes. Stimulation was discontinued if contractions occurred. If contractions did not occur, the same protocol was repeated after a 2-minute rest period for up to three cycles. If there was still no uterine activity, the patient first performed unilateral stimulation for 10 minutes, followed, if necessary, by bilateral stimulation for another 10 minutes. When uterine activity subsided, we discontinued monitoring.

All patients had management by resident and staff physicians who did not know the mammary stimulation test results. The primary outcome measure, which was chosen a priori, was preterm delivery, which we defined as delivery before 37 completed weeks' gestation by best obstetric estimate. Secondary outcome measures included preterm labor, the need for tocolysis, and test-to-delivery interval.

Contingency tables were constructed to evaluate the relationship of mammary stimulation test results to outcome measures. In exploratory analyses, differences in continuous variables were evaluated by the Student t test, and categoric variables were evaluated by χ^2. We used discriminant analyses, which included the independent variables of candidate clinical risks and mammary stimulation test results and the dependent variables of preterm delivery and preterm labor, to determine whether mammary stimulation test results provided information beyond that available from clinical risks. A p value of <0.05 was considered significant.

Results

Of the 94 patients in the study sample, 19 (20%) had preterm delivery. Clinical characteristics, antepartum risks, and mammary stimulation test results (independent variables) are shown in Table I. As we anticipated, preterm delivery was preceded by an excess of recognized antepartum medical and obstetric risk factors. The preterm and term delivery groups did not differ in the gestational duration (approximately 28.5 weeks) at which the mammary stimulation test was performed. However, the mammary stimulation test was positive about twice as frequently among the patients who had preterm delivery than among those who were delivered at term (84% vs 41%, respectively). Table II documents pregnancy outcomes, including the primary and secondary outcome measures (dependent variables). Among the 19 patients who were delivered before term, only one infant died in the neonatal period. There were no complications attributable to mammary stimulation test testing.

Negative predictive value	83%		
At risk	50%		
Explained variance	12%		

Relationships of mammary stimulation test results to the primary and secondary outcome measures are shown in the contingency tables (Tables IIIA, IIIB, and IIIC). The odds that a patient with a positive mammary stimulation test would be delivered before term were increased 7.6-fold. A positive mammary stimulation test correctly identified 16 of the 19 patients who were delivered before term (sensitivity = 84%). In addition, a negative test preceded term delivery in 44 of 47 patients (negative predictive value = 94%). Among the three patients with negative mammary stimulation tests who were delivered before term, delivery occurred after 34 weeks' gestation, none had a test-to-delivery interval of <5 weeks. Furthermore, all babies born to mothers with negative mammary stimulation tests weighed >2000 gm.

Mammary stimulation test results were related to the occurrence of preterm labor with a strength similar to that for preterm delivery (explained variance = 12%). No patient with a negative mammary stimulation test was delivered during the month after the test (positive predictive value = 100%), and all patients who were delivered during the succeeding month had a positive mammary stimulation test (specificity = 100%).

To evaluate the potential role of the mammary stimulation test in clinical care, test results were related to preterm delivery in patients with the major risk factors shown in Table I. The results of this analysis are shown in Table IV. Limiting use of the mammary stimulation test to high-risk patients doubles the explained variance (24%) of the classification. However, comparing Tables IIIA, IIIB, IIIC, and IV reveals that six patients who were delivered before term did not have major high-risk factors and that five of these had positive mammary stimulation tests.

Finally, to better understand the relationship of mammary stimulation test results and clinical factors as potential predictors of preterm outcomes, we per-

formed two discriminant analyses, that allowed the clinical factors to be entered before the mammary stimulation test results. In addition to demographic data, clinical factors included the risk factors indicated by asterisks in Table I. Two antenatal risk factors, previous preterm delivery and late prenatal care, contributed significantly to the classification of preterm delivery [F (2,91) = 8.9, R^2 = 16.4%]. The mammary stimulation test significantly improved the classification by adding an additional 7.7% of explained variance [F (3,90) = 9.5, R^2 = 24.1%]. Four clinical factors contributed significantly to the classification of preterm labor [F (4,89) = 12.4, R^2 = 35.8%]. The mammary stimulation test significantly improved this classification, as well, by adding an additional 5.2% of explained variance [F (5,88) = 12.3, R^2 = 35.8%]. The resulting jackknifed classifications are shown in Tables VA and VB.

Comparison of Table VA with Table IIIA reveals that, although including clinical risks doubles the explained variance and improves the specificity from 59% to 91%, six cases of preterm birth, which are correctly classified by the mammary stimulation test alone, are misclassified when clinical risks are taken into account, thereby decreasing the sensitivity from 84% to 53%. Comparing Table IIIB with Table VB reveals that considering clinical risks improves the positive predictive value from 49% to 73% and the specificity from 62% to 87% without substantially diluting the sensitivity.

Comment

The key finding in this study is that a new provocative test, the mammary stimulation test, predicts preterm delivery and can be used to predict both preterm labor and not being delivered within 1 month of testing. In addition, the mammary stimulation test provides more extensive information than do the usual clinical risk factors considered useful for identifying patients destined to deliver before term.

The seed that led to our development of the mammary stimulation test derived from exposure of one of the authors (R.J.S.) to a technique used by Drs. Arpad Csapo and Jacques Sauvage at Washington University in St. Louis more than two decades ago. Uterine response to oxytocin challenge was used as a marker of the evolution of uterine contractility[18] to predict whether induction of labor would be successful and to

Risk factors include: mammary stimulation test results, gravidity, abortions, multiple gestation, and previous preterm delivery.

answer the question, "Is the myometrium in a state that is ready for labor?"

During the past two decades, substantial research has been used to explain the basis for the evolving uterine response to oxytocin challenge.[19] It appears that uterine sensitivity to oxytocin increases with advancing gestational age as a result of an increase in the number and effectiveness of myometrial oxytocin receptors.[20-22] Because oxytocin sensitivity increases before the onset of labor, several investigators have correlated uterine activity, oxytocin sensitivity, and perterm labor and delivery.[19] Uterine activity and oxytocin sensitivity are increased in patients who are delivered before term.[23-26] Finally, a separate line of research indicates that nipple stimulation results in oxytocin release and elevation of plasma levels of oxytocin.[27-29] As a result of these studies, we speculate that in patients destined to be delivered before term, the mammary stimulation test reveals the state of the myometrium as marked by increased sensitivity to oxytocin endogenously released by nipple stimulation.

The results presented here should be interpreted cautiously. This initial series of patients is small. Validation in larger samples with different demographic characteristics will be necessary. In particular, the utility of the mammary stimulation test must be tested in samples with lower prevalences of preterm labor and delivery. An additional caveat is that the initial criterion for mammary stimulation test positivity was simply stated in the study protocol as "the presence of uterine contractility." More specific criteria were derived heuristically by one of the investigators (R.D.E.) in conjunction with interpreting the tracings. The resulting criteria are shown in Table VI. To be classified as a positive mammary stimulation test, uterine activity (contractions >40 seconds in duration) should be noted before the onset of stimulation (Fig. 1) or in response to nipple stimulation before the end of the second 2-minute rest period (Fig. 2). To be classified as a negative mammary stimulation test (Fig. 3), uterine activity should not be observed before the end of the second rest period (8 minutes after the onset of unilateral breast stimulation). In this series all mammary stimulation tests that became positive did so before 8 minutes after the onset of unilateral stimulation. Although interpretation of the tracings was entirely blinded as to clinical outcome, these recommended criteria also require validation.

Table VI. Mammary stimulation test criteria

1. Positive test
   a. Any spontaneous uterine contraction(s)>40 seconds before initiation of nipple stimulation
   b. Any uterine contraction(s) of >40 seconds by completion of two stimulation cycles (8 minutes from the onset of stimulation)
2. Negative test
   Absence of uterine activity [contraction(s) that last for >40 seconds before or during stimulation.

Despite the caveats noted in the previous paragraph, the mammary stimulation test appears to have considerable promise for clinical application. It appears to be more sensitive in detecting risk for prematurity than

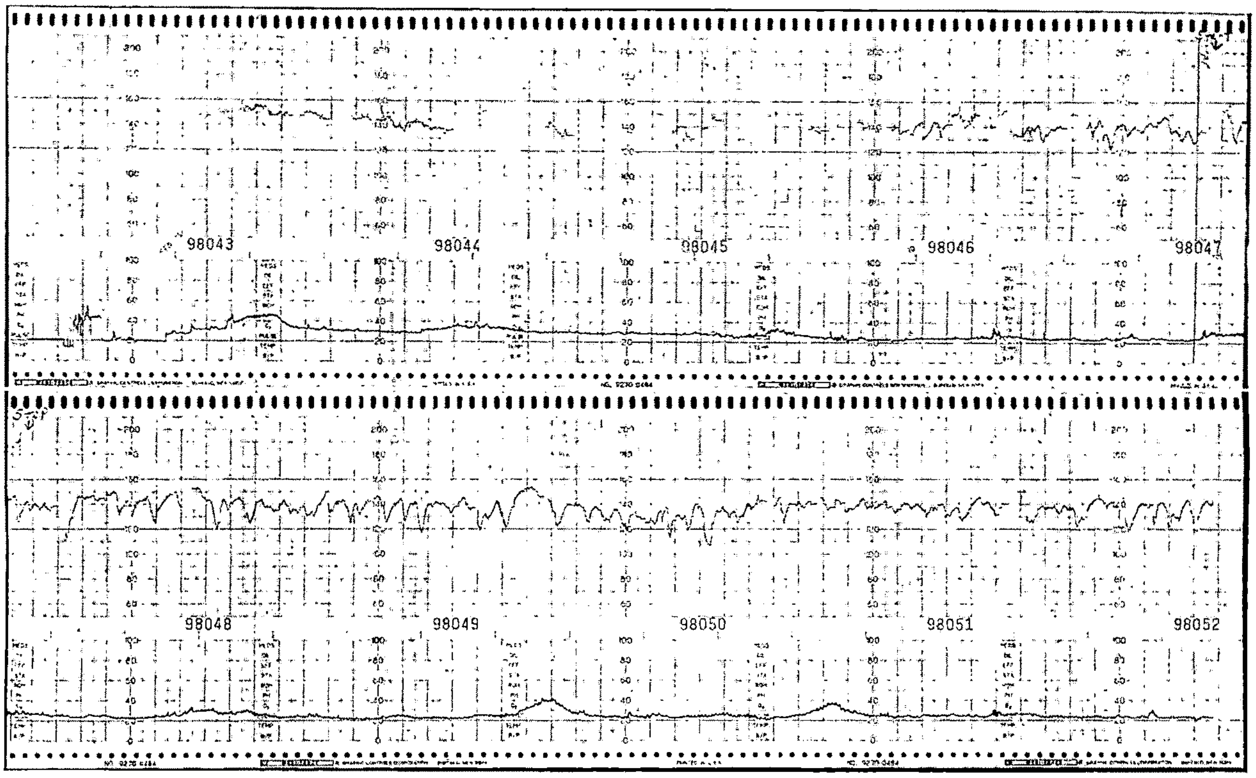

Fig. 1. Spontaneous positive mammary stimulation test. Spontaneous uterine contraction(s) are noted before initiation of nipple stimulation.

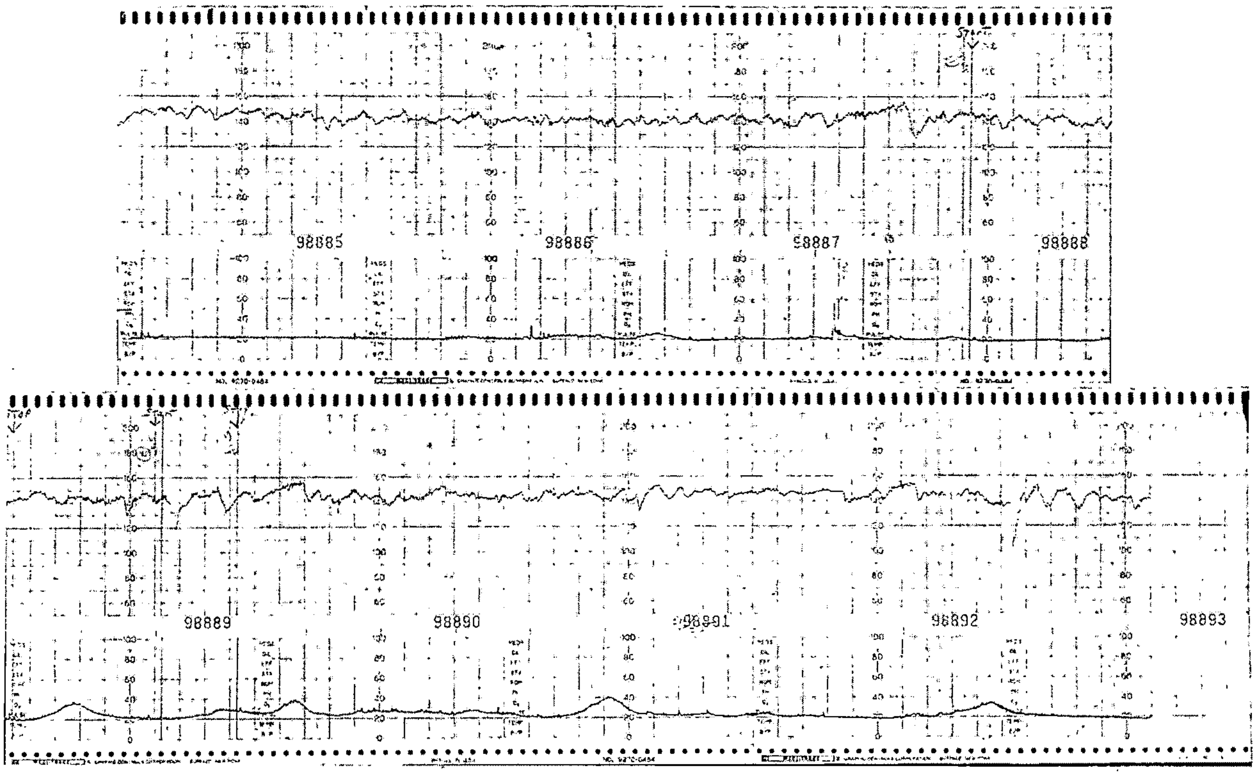

Fig. 2. Positive mammary stimulation test. Uterine contractions are noted by completion of two stimulation cycles.

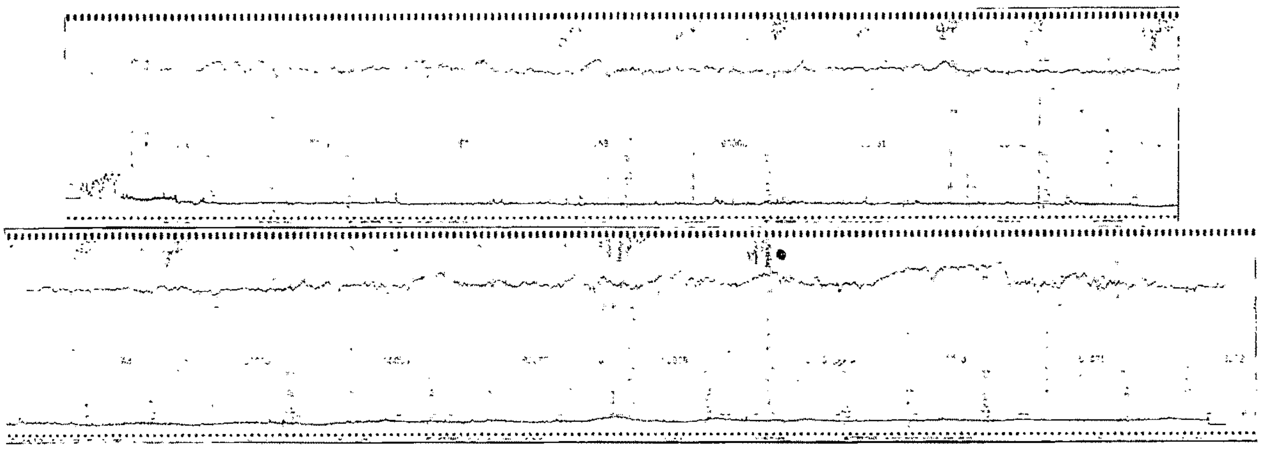

Fig. 3. Negative mammary stimulation test. Absence of uterine activity before or during stimulation.

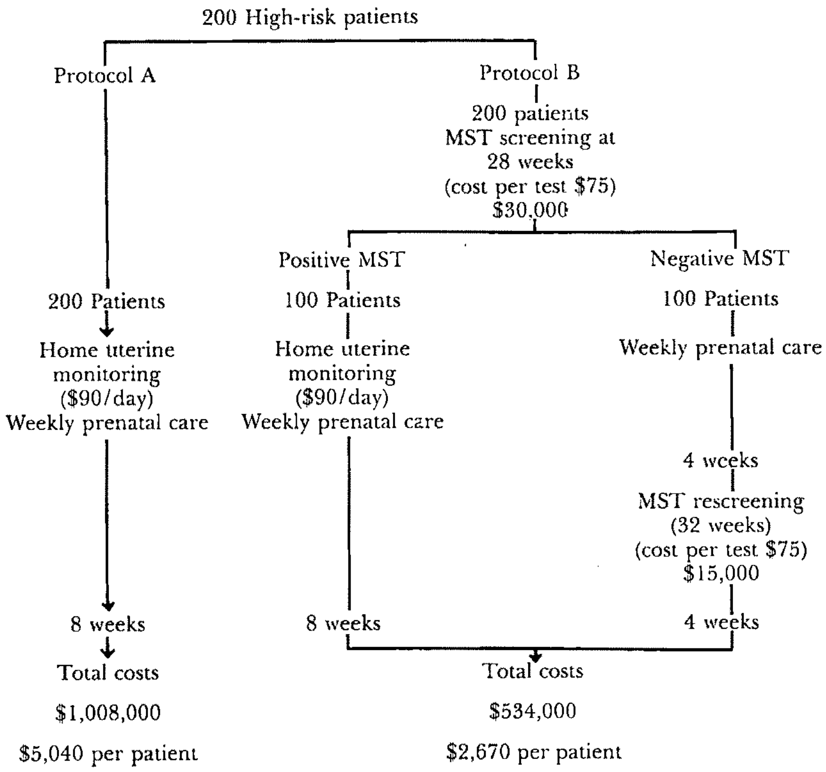

Fig. 4. Potential cost savings of home uterine activity monitoring when preceded by mammary stimulation test *(MST)* screening.

are clinical factors. The nipple stimulation and monitoring methods[17] are well validated and safe and currently are widely used in clinical practice to perform contraction stress tests. Performing the mammary stimulation test usually requires about 20 minutes, which is a duration between that needed for fetal nonstress testing and that for contraction stress testing. In addition, the mammary stimulation test appears to reliably identify patients who will *not* be delivered prematurely. Thus it appears that mammary stimulation test testing could be a highly cost-effective component of prematurity prevention.

Currently, formal prematurity prevention programs consist of clinical risk assessment, patient behavioral modification, and ambulatory uterine activity monitoring. The most controversial and the most expensive of these techniques is ambulatory uterine activity monitoring, and its contribution to prematurity prevention is controversial. With a method such as the mammary stimulation test, which is more accurate than clinical risk assessment in predicting preterm delivery, the numbers of patients requiring daily uterine activity monitoring might be reduced, and cost-effectiveness might be improved.

Fig. 4 depicts a cost analysis of an ambulatory uterine activity monitoring program both with and without mammary stimulation test screening, it uses assumptions that are based on observed rates in the current series. Monitoring is routinely begun at 28 weeks' gestation and continues for 8 weeks in a hypothetical sample of 200 patients at risk for preterm delivery. Under protocol A, all patients are monitored at home at a cost of $90 per day, which results in a total cost in excess of $1 million. However, if mammary stimulation test screening is used at 28 weeks at a cost of $75 per test to determine risk status, 100 patients (those with negative mammary stimulation tests) do not require home uterine activity monitoring (protocol B). Because the predictive value of a negative mammary stimulation test persists for at least 5 weeks, patients are retested in 1 month (32 weeks) to reevaluate risk status. The net savings of the mammary stimulation test screening program are nearly half the cost of an ambulatory uterine activity monitoring program.

In conclusion, the mammary stimulation test appears to have the theoretical rationale, predictive utility, simplicity, safety, and low cost that recommend additional study to determine whether it should play a major role in the care of pregnant women.

Discussion

Dr. Washington C. Hill, Nashville, Tennessee. Predicting which patients will develop preterm labor or will be delivered before term is, at this time, fair at best. Eden and co-workers have joined the ranks of many of us in trying to devise a method to predict which myometrium is susceptible to going into labor before term. They do this by designing a new test with new initials, the MST, thereby adding another eponym of obstetrics (EOO) to an already crowded perinatal alphabet soup (FCI, L/S, AST, CST, OCT, BSST, D/A, PTL, NST, AFV, FAD, PUBS, FSI, A/B, S/D, FBP, etc.). This test utilizes the breast stimulation stress test in attempting to predict which patients may develop preterm labor or have preterm delivery.

It will be difficult at best for any one test, clinical evaluation, or system to predict preterm labor or preterm delivery. The individual methods alone are simply not sensitive enough or do not have a high enough positive predictive value. A combination of these methods in forming a preterm labor screening index will probably be more successful.

I would like to critique this article by looking at the five characteristics, mentioned by the authors, that make [this topic] worthy of further study: theoretical rationale, predictive utility, simplicity, safety, and low cost.

The theoretical rationale of the mammary stimulation test is based on a difference in the myometrium that will go into labor early versus the myometrium that will progress into labor at term. It is theorized that there are more numerous or more sensitive oxytocin receptors in the former. Data suggest that this may indeed be the case. There is, however, a difference between (a) using known amounts of exogenous oxytocin to see if the uterus is ready for labor and (b) using unknown amounts of endogenous oxytocin produced by nipple stimulation to see if preterm labor will develop or preterm delivery will occur. Point a is not equal to point b.

Eenie, meenie, mini, mo: What do the data really show about predictive utility? The reader is bombarded with many statistics: positive predictive value, sensitivity, specificity, negative predictive value, percent at risk, χ^2, explained variance, relative risk, odds ratio, p value, jackknifed classifications, discriminant analysis, and contingency table. The "bottom line" appears to be that with a small number of patients the sensitivity, specificity, positive predictive value, and negative predictive value of the mammary stimulation test are in the same range as those of other reported methods devised for predicting preterm labor or preterm delivery. In fact, in assessing the predictability of the mammary stimulation test, risk scoring is also used. The ability to predict preterm delivery or term delivery is also affected and confused by introducing and confounding variable of tocolytic therapy. Some patients who had a positive mammary stimulation test and subsequently were delivered before term or at term had tocolytic therapy. The same is true for some who had preterm labor.

The predictive value of a negative mammary stimulation test for preterm delivery was very high in this small number of patients, but it certainly was not reliable enough in this preliminary report to eliminate home uterine activity monitoring from a prematurity prevention program because three patients were delivered preterm. The real negative predictive value has yet to be determined.

The mammary stimulation test is simple and easy to perform. As with the breast stimulation stress test, there will be patients who prefer not to stimulate themselves. Although the test is simple, will it be useful or predictive?

I don't know if the mammary stimulation test is safe; it may be, but there are no data on the interval from the administration of the mammary stimulation test to the onset of preterm labor. Could the mammary stimulation test (performed correctly or incorrectly) cause preterm labor, preterm delivery, or both in higher-risk patients? Which came first, the chicken or the egg? Could performing the mammary stimulation test cause hyperstimulation? As the authors mentioned, it is necessary to study more patients with variable risks to answer these and other important questions.

The test is inexpensive, but this is only one variable in determining its real value. An inexpensive useless test is still a useless, cheap test.

I agree with the authors that the final verdict on the mammary stimulation test is not in yet and that we should be cautious in interpreting this limited experience. I have the following questions for them, whom I commend for winning the Annual Prize Award and for making an excellent attempt in tackling a very difficult problem that is elusive to many investigators.

1. The authors note that *no* patients with a negative mammary stimulation test were delivered before 34 weeks or had a baby weighing <2000 gm. What was the similar breakdown for patients with a positive mammary stimulation test?
2. What was the interval from the mammary stimulation test to the onset of preterm labor?
3. What was the regimen of tocolysis, and how do the authors deal with this confounding variable when interpreting their data?
4. How was preterm labor defined?
5. All studies reporting on the breast stimulation stress test have involved hyperstimulation. What was the incidence in this study?
6. How early could this test be used?

Dr. Randall T. Kelly, Dearborn, Michigan. I do not feel that this article will cause a revolution in perinatal medicine, but I do feel that the practice of obstetrics will change in the future as a result of the authors' pioneering work on uterine contraction activity testing. The article deserves little criticism, but there are a few things that I would like to discuss.

If a test in medicine is to be universally performed, as I feel that this one (or something similar to it) will be on all pregnant patients, then nomenclature that is more easily accepted and understood by physician and layman alike will help us to maintain that test in the public domain. In addition, pregnant patients will be more willing to accept it as a routine test of pregnancy. Perhaps a better name for the test would be the breast stimulation test for preterm labor or the nipple stimulation test for preterm labor. In any case, removal of the word *mammary* would be helpful, because many of our patients do not know what that word means. I think that there should be something about preterm labor in the name of the test.

In the first paragraph of the article, Dr. Eden states that with all of our current programs, there has been no decrease in the incidence of prematurity. This is true. The problem is, though, that many patients have no access to any program, no discussions about preterm labor and its symptoms are provided during prenatal care.

In the Methods section, a reference is listed for the standard protocol of nipple stimulation contraction stress testing. This reference, which is from Dr. Eden and Dr. Boehm's textbook, does not have a protocol for the nipple stimulation contraction stress test in that chapter as listed in the reference.

There is a big range of gestational ages in this study (24 to 32 weeks). One could say that sensitivity to oxytocin or other hormones could differ significantly at 24 weeks when compared with 32 weeks, and so using fetuses of one gestational age would make a "cleaner" study.

Exactly how the nipple is stimulated is not discussed, nor is whether the stimulation is continuous for the 2-minute period. Stimulation was discontinued if contractions occurred. Later, it appeared that even one contraction was sufficient for discontinuation. There should be a discussion of criteria regarding these contractions, and what is considered a positive or a negative mammary stimulation test should be established.

I also have a few questions. In Table I, did the patients with cervical incompetence have a cerclage? This should be delineated. In Table II only 6 of the 19 patients who were delivered before term had preterm labor. Were some patients delivered early because of a medical problem, such as severe preeclampsia, which might make the uterus more sensitive to oxytocin at that stage of pregnancy? This should be discussed.

There is a statement that nipple stimulation results in oxytocin release and in an increase of plasma levels of oxytocin. This is still a slightly controversial point that could have been examined with plasma oxytocin levels in this study. Perhaps a plasma oxytocin level, prostaglandin level, or prostaglandin metabolite level at a certain stage in pregnancy will be our future test with better sensitivity.

The overall series is small. The authors realize this. The participants in the study were not randomly selected; this limits the ability to generalize the findings. The study considers a group of patients who are at an extremely high risk for preterm labor. Another study on groups with a much lower risk for preterm labor (and thus perhaps with fewer confounding variables, such as poor socioeconomic status, previous preterm delivery, and late prenatal care) would make a much "cleaner" study. Again, the criteria for positive and negative tests are not dealt with until the Comment section and Table VI. Even though the criteria for contractions and positive and negative testing were originated heuristically, I feel that they should have been discussed in the Methods section so that the reader would understand the remainder of the article without having to read it many times.

The statistical analyses are complete and appropriate for the type of data collected and for the nature of the research project, but the authors often did not explain or discuss the statistics or the analyses sufficiently. More description and interpretation of the tables would have been useful and would have made the data more understandable to the reader. Very specific data are provided with minimal comments in the tables.

The authors do state that the results of the study should be interpreted cautiously. I agree with this. However, I do feel that this is a good solid pilot study. In the future a test similar to the mammary stimulation test, as described here, or some other test along the same lines will be routine for all obstetric patients.

DR. ROBERT J. CARPENTER, Houston, Texas. One thing I didn't see was a breakdown of singleton versus twin gestations and their data base. I would like to have some information on that and on how the removal of twins may change the data.

DR. WILLIAM J. OTT, St. Louis, Missouri. I would like to congratulate the authors on their excellent pilot study and in trying to predict those patients at risk with premature labor.

I have one question, however, about the statistical analysis of their data. The positive and negative predictive values of any test are significantly influenced by the incidence of the disease process in question. I want to know whether Bayesian analysis was used to correct for this in determining positive and negative predictive values, because this may significantly alter the values of the positive and negative tests.

DR. SUZANNE R. TRUPIN, Champaign, Illinois. Were cervical examinations done on these patients? If so, were there any criteria for eliminating patients from the study or for determining a difference in responsiveness to the mammary stimulation test in patients with cervical effacement? Also, was there a difference between the multiparous patient and the nulligravid patient in response to this test?

UNIDENTIFIED SPEAKER, St. Louis, Missouri. I enjoyed the presentation. It is refreshing to have the results of some form of testing for preterm labor that will not increase (and may decrease) the use of home uterine activity monitoring.

I have two questions. One has to do with the incidence of preterm delivery in the group of patients from the same clinic who did not undergo any mammary stimulation testing. What is the baseline in the true control group?

Second, preterm labor really results from a hodgepodge of different causes, and I would like to have a breakdown, if possible, regarding patients who had placental complications with bleeding manifestations in preterm labor, membrane rupture in preterm labor, and also intact membranes with preterm labor, because there may be different abilities to predict these different causes of the actual birth event.

Dr. Eden (Closing). We like to thank the reviewers for their comments, especially that regarding alphabet soup.

Because we believe that the mammary stimulation test will, in fact, prove to be clinically useful, we agree that it is imperative that the test be given a simple, catchy, and easy-to-remember name. Our biggest dilemma was, in fact, deciding on the name of this provocative new test.

We also agree with the concerns raised regarding the predictive ability of the mammary stimulation test, and we are currently expanding the series considerably. Our fondest hope is that other institutions and investigators will attempt to verify our findings, and thus will enable the mammary stimulation test to take its place in prematurity prevention programs.

Three minutes will not permit me enough time to comment on all the questions, but I would like to address a couple of Dr. Hill's queries first.

We analyzed the patients who were delivered prematurely with respect to the negative mammary stimulation test. One patient was delivered at 34 weeks. The other two were in the thirty-fifth and thirty-sixth weeks of pregnancy, respectively, and all three of these premature infants weighed >2000 gm at birth.

Of the 16 patients with positive mammary stimulation tests, 9 gave birth to infants weighing <2000 gm, with weights ranging between 1250 and 1920 gm. Ten of the infants of these 16 women were born at ≤34 weeks' gestation.

In positive mammary stimulation tests the interval from the time of the mammary stimulation test to delivery was about 4 weeks. In negative mammary stimulation tests, this interval was approximately 9 weeks. The regimen of tocolysis was basically a standard protocol that is used on the labor and delivery unit by residents. The diagnosis of preterm labor basically requires either cervical change or documentation of uterine contractions (eight or more per hour) on the monitor. Intravenous tocolysis is accomplished by administering either magnesium sulfate or a β-sympathomimetic, such as terbutaline, followed by intravenous hydration.

We had no evidence of uterine hyperstimulation in this small series. That is probably a result of light stimulation and cessation of the test when contractions occurred. The alternative would have been to go to the end of the contraction stress test, which requires three contractions in 10 minutes and additional stimulation.[17]

The earliest that we started patients on the mammary stimulation test protocol was 24 weeks, because that is probably the earliest time at which the test can be performed, as a result of the limitations of the equipment (specifically, the sensitivity of that equipment to detect uterine contractions).

The data for twin gestations showed similar outcome measures. In fact, the two patients with twins who were delivered at term had negative mammary stimulation tests, although all patients who were delivered before term had positive mammary stimulation tests. Patients with premature rupture of the membranes had test results similar to those of patients without premature rupture of the membranes.

The incidence of preterm delivery in our patient population is related to our location. We have a very interesting patient population in the city of Detroit, as a result of the problems associated with access to prenatal care. We have approximately a 20% to 25% incidence of preterm labor or preterm delivery, or both, which unfortunately is very, very high.

We chose 5 weeks as the minimum because prenatal care usually requires that the patients be examined at 3- to 4-week intervals until late in gestation. Therefore a 5-week interval of time provides some degree of safety.

In originating the mammary stimulation test, we felt strongly that nipple stimulation was preferable to the cumbersome technique of intravenous oxytocin administration, which patients do not readily accept. However, we do agree that knowing the oxytocin levels and being able to standardize oxytocin administration are preferable.

All patients were seen after pelvic examination. In our preterm labor clinic all patients are examined by residents with staff supervision. No patient had advanced cervical dilatation, and there was minimal concern about gravidity.

A randomized trial evaluating leuprolide acetate before hysterectomy as treatment for leiomyomas

Thomas G. Stovall, MD, Frank W. Ling, MD, Louie C. Henry, MD, and Marie R. Woodruff, RN
Memphis, Tennessee

Fifty premenopausal patients requiring hysterectomy as treatment for symptomatic uterine leiomyomas, which were the size of 14 to 18 weeks' gestation, were randomized into two groups to determine whether preoperative gonadotropin-releasing hormone agonist would increase the feasibility of vaginal rather than abdominal hysterectomy. The control group (group A; $n = 25$) did not receive preoperative gonadotropin-releasing hormone agonist, but patients in Group B ($n = 25$) received 2 months of gonadotropin-releasing hormone agonist before undergoing hysterectomy. Patients in the two groups were similar with respect to age, gravidity, parity, pretreatment uterine size, and hemoglobin and hematocrit levels. Patients in group B had an increase in hemoglobin levels (10.75 to 12.12 gm/dl, $p < 0.05$) and a decrease in uterine volume (1086.7 to 723.4 ml, $p < 0.05$) after 8 weeks of agonist therapy and were more likely to undergo vaginal hysterectomy (76.0% vs 16%). Patients in group B also had shorter hospitalizations (5.2 vs 3.8 days, $p < 0.05$). We conclude that the administration of gonadotropin-releasing hormone agonist for 2 months followed by vaginal hysterectomy is preferable to abdominal hysterectomy in selected patients with uterine leiomyomas. (AM J OBSTET GYNECOL 1991;164:1420-5.)

Key words: Leuprolide acetate, hysterectomy

When compared with abdominal hysterectomy, vaginal hysterectomy is associated with significantly fewer complications, less febrile morbidity, and the need for fewer transfusions. In addition, patients require shorter hospital stays and have a shorter convalescent period.[1] Uterine morcellation or intramyometrial coring techniques allow vaginal removal of uteri >700 gm.[2, 3] Despite the advantages of vaginal hysterectomy, some leading authorities in gynecologic surgery do not recommend vaginal hysterectomy when the uterus is larger than 10 to 14 weeks' gestational size.[4]

Many studies now show that administration of gonadotropin-releasing hormone (GnRH) agonist reduces both leiomyoma size and uterine volume and that the majority of this reduction occurs within the first 8 weeks of treatment.[5-9] The purpose of this study was to determine whether short-course preoperative GnRH agonist therapy before planned hysterectomy as treatment for uterine leiomyomas could result in increased performance of vaginal hysterectomy. We also wished to determine if this treatment would be associated with a decrease in morbidity, hospital stay, or convalescent period.

Material and methods

Premenopausal women with symptomatic uterine leiomyomas who did not desire future fertility voluntarily consented to participate in this study, which was approved by the University of Tennessee Institutional Review Board. Inclusion criteria included: (1) premenopausal status (follicle-stimulating hormone level <30 mIU/ml); (2) the absence of pregnancy or lactation; (3) the presence of fibroids 14 to 18 weeks' gestational size on pelvic examination; (4) the absence of uterine calcification on ultrasonographic examination; (5) significant symptoms including menorrhagia, pelvic pressure, or pelvic pain; (6) no suspicion of ovarian or uterine malignancy on physical or ultrasonographic examination; (7) benign endometrial histologic features (if endometrial sampling was clinically indicated).

Patients were randomized to either immediate hysterectomy (group A) or to preoperative GnRH agonist treatment (group B). Patients in group B received GnRH agonist in one of two forms according to its availability: either depot leuprolide acetate 3.75 mg (TAP Pharmaceuticals, North Chicago) intramuscularly every 4 weeks for two injections (8 treatment weeks) or

Table I. Comparison of demographic and pretreatment data between groups A and B

Characteristics	*Group A (n = 25)*	*Group B (n = 25)*	*p Value*
Age (yr)	39.5 ± 6.2 (30-51)	39.8 ± 5.6 (31-51)	NS
Gravidity	2.81 ± 2.2 (0-8)	2.69 ± 2.1 (0-8)	NS
Parity	2.41 ± 2.0 (0-6)	2.42 ± 1.9 (0-7)	NS
Pretreatment* hemoglobin (gm/dl)	11.17 ± 2.0 (8.1-15.2)	10.75 ± 2.2 (6.7-14.3)	NS
Pretreatment* hematocrit (%)	34.5 ± 4.4 (29.4-44.1)	33.2 ± 5.8 (23.4-44.0)	NS

NS, Not significant. Values are mean ± SD. Ranges are shown in parentheses.

*Pretreatment hemoglobin and hematocrit levels in group A are also the preoperative laboratory values.

0.5 mg/day subcutaneously daily for 8 weeks. Patients in group A underwent hysterectomy within 4 weeks of their randomization, and patients in group B underwent hysterectomy either 5 weeks after the last depot injection or 1 week after the last subcutaneous injection. GnRH treatment was initiated on menstrual day 2 to 4 in all patients. Blood samples for determination of serum estradiol FSH, luteinizing hormone hemoglobin, and hematocrit were obtained before treatment and at weeks 4 and 8.

Ultrasonographic measurements of fibroid and uterine dimensions were performed with an Acuson 128 machine with a 3.5 MHz transducer (Acuson, Inc., Mountview, Calif.). The uterine fundus was measured in three dimensions: anteroposterior dimension, width, and length (from internal os to top of fundus). Uterine volume was calculated by a previously described formula.[5] All patients in group B had pretreatment and posttreatment ultrasonography, and patients in group A had only pretreatment (preoperative) ultrasonography. Patients in group B underwent a bimanual examination before treatment and at weeks 4 and 8.

All patients in this study were considered eligible for vaginal hysterectomy if the uterus was mobile and was ≤14 weeks' gestational size on bimanual examination. Hysterectomies were performed by a senior gynecology resident and two authors (T.G.S., L.C.H.). All patients received a single 2 gm prophylactic dose of cefazolin before induction of anesthesia. Total blood loss was determined by weight in the following way: Total blood loss = (Blood measured from suction [milliliters] minus Irrigation used [milliliters]) plus (Wet sponge weight minus Dry sponge weight [grams]) divided by 1.06 gm/ml (Blood density). Total surgical time and operative complications were recorded. All uteri were weighed on the same scales at the time of surgery. Uterine volume was determined by water displacement at the time of surgery. Data were collected postoperatively on the number of blood transfusions, febrile morbidity, postoperative complications, length of hospital stay, and length of convalescence (time from surgery until the patient felt she could return to her normal activities).

Data were analyzed with the Student *t* test; $p < 0.05$ was considered significant.

Results

Fifty patients were eligible for study inclusion. Twenty-five patients were randomized to group A (immediate hysterectomy), and 25 patients were randomized to 2 months of leuprolide acetate before hysterectomy (group B). The two groups were similar with respect to age, gravidity, parity, and pretreatment hemoglobin and hematocrit levels (Table I).

The groups did not differ with respect to either pretreatment uterine size as measured by pelvic examination or ultrasonographically measured uterine volume (Table II). After GnRH therapy patients in group B had a reduction in uterine size from 15.7 to 11.2 weeks' mean gestational size as determined by pelvic examination ($p < 0.05$). Uterine volume on ultrasonographic measurement also decreased from a mean of 1086.7 to 723.4 ml ($p < 0.05$) after 2 months of leuprolide therapy and was not dependent on which of the two forms of the drug was used. Both preoperative uterine volume and uterine weights were lower in group B than in group A after agonist therapy, but these differences in volume and weight did not reach statistical significance (Table II).

Pretreatment and preoperative hemoglobin and hematocrit levels in group A were similar to the pretreatment levels in group B (Table I). However, patients in group B had an increase in both hemoglobin and hematocrit levels during the 2-month treatment period. Hemoglobin levels increased from a mean of 10.75 ± 2.2 gm/dl to a mean of 12.12 ± 1.1 gm/dl ($p = 0.03$), and the mean hematocrit increased from 33.2% ± 5.8% to 37.14% ± 2.8% ($p = 0.03$).

As a result of uterine size more than 14 weeks' gestation, 21 of 25 patients (84%) in group A underwent abdominal hysterectomy, although only 4 (16%) were

Table II. Comparison of uterine volume data between groups A and B

Characteristics	*Group A* (n = 25)*	*Group B (n = 25)*	*p Value*
Pretreatment uterine size (gestational wk)	15.4 ± 1.2 (14-18)	15.7 ± 1.4 (14-18)	NS

*Pretreatment and preoperative values are the same for group A.
†Statistically significant.

considered candidates for vaginal hysterectomy. Two of four patients who underwent vaginal hysterectomy required uterine morcellation. In group B none of the patients were thought to be candidates for vaginal hysterectomy before leuprolide acetate therapy because all uteri in group B were >14 weeks' gestational size. After agonist therapy, 19 of 25 patients (76.0%) had uteri ≤14 weeks' gestational size, they were considered candidates for and underwent vaginal hysterectomy. Although all patients in this group had uteri ≤14 weeks' gestational size, four patients did not have the uterine mobility to undergo vaginal hysterectomy, and two patients experienced a failed attempt at vaginal hysterectomy and required abdominal hysterectomy. In one patient, although the uterus was small after agonist therapy, the uterus and bladder were densely adhered to the abdominal wall. This patient had an inadvertent cystotomy, which was repaired abdominally. In the other patient the cul-de-sac was obliterated with adhesions; this resulted in inadvertent sigmoid colon injury that was repaired vaginally.

There was no statistical differences in mean operative time, blood loss, or postoperative hemoglobin or hematocrit levels between patients in groups A and B (Table III). No patient required intraoperative or postoperative transfusion. However, patients in group B had significantly shorter postoperative hospital stays and convalescence periods than did patients in group A (Table III).

Comment

Selected patients with enlarged uteri that are 14 to 18 weeks' gestational size as a result of leiomyomas can safely undergo vaginal hysterectomy when GnRH agonist is used as a preoperative surgical adjuvant. This method of reducing uterine size not only is safe but also allows a greater number of patients to undergo vaginal hysterectomy. Although other authors have described removing even larger uteri vaginally,[3] in this study we used a uterine size of 14 weeks' gestation as the upper limit at which to attempt vaginal hysterectomy. Regardless of the uterine size used by the individual surgeon as a limiting factor in his or her practice, the data here suggest that preoperative agonist therapy may allow vaginal removal of a greater number of uteri.

Patients who received GnRH agonist were treated for 8 weeks before to surgery. This length of therapy was chosen because the majority of uterine size reduction occurs by approximately 8 weeks of therapy, although a small amount of reduction continues for several additional weeks.[7-8] With short-term therapy of only 2 months, there should be no concerns about bone loss, the patient can better tolerate the hypoestrogenic side effects, and the costs associated with agonist therapy are kept to a minimum.

For the patient with significant vaginal bleeding that results in anemia, this form of therapy has an additional benefit. Because the majority of patients treated with GnRH agonist therapy experience amenorrhea, concomitant iron therapy results in an increase in hemoglobin and hematocrit levels. Patients in group B demonstrated this anticipated increase. Although there was not a statistically significant difference in operative time, there was an average decrease of 71 ml of blood loss in those patients in group B when compared with those in group A. This decreased blood loss, although it is statistically significant, may or may not be of clinical significance in the selected patient.

Although uterine weights at the time of surgery in groups A and B were not statistically significant ($p > 0.05$), the difference in mean weight of 406.8 gm in group A patients and 341.8 gm in group B patients was apparently of clinical significance, because an increased number of patients in group B were able to undergo vaginal hysterectomy. Because agonist therapy resulted in a reduction both in average estimated urine size on pelvic examination from 15.7 to 11.4 weeks and in ultrasonographic volume from 1086.7 to 723.4 ml, it appears that agonist therapy may result in a greater reduction in uterine volume than in uterine weight. This hypothesis cannot be tested because uterine volume can be measured before and after treatment, but weight can be determined only after the uterus is removed.

The cost of 2 months of leuprolide acetate therapy at our institution ranges from $350 to $600, depending on whether patients are able to share the cost of a vial of drug and whether the patient chooses to use the daily injection or the depot form. This cost, however, is offset by a decreased length of hospital stay and a decreased length of convalescence, which reduce time lost from work. Future studies may show that estrogen replacement therapy can be used to decrease the hypoestrogenic side effects associated with GnRH agonist therapy without offsetting the benefits of uterine size reduction.

This study demonstrates that selected premenopausal patients with uterine leiomyomas of 14 to 18 weeks' gestational size can safely undergo vaginal hysterectomy when they are treated with a short course of leuprolide acetate before surgery. This method appears to have advantages over abdominal hysterectomy because it is associated with a shorter postoperative hospital stay and an overall decrease in the postoperative convalescent period. This technique also appears to allow time for the successful treatment of significant anemia without the risk of transfusion. The results of this study indicate that preoperative GnRH agonist therapy for 2 months before planned vaginal hysterectomy for the patient with uterine leiomyomas of 14 to 18 weeks' gestational size can be recommended.

Discussion

DR. Bob L. SHULL, Scott & White Hospital, Temple, Texas. In 1989 Schlaff et al.[1] used a placebo-controlled trial to show that GnRH agonist therapy produced a significant reduction in total uterine volume and in nonmyoma volume but that it did not produce a significant reduction in myoma volume.[1] They did not, however, address the specific question of how much volume is too much to prevent vaginal hysterectomy.

Friedman and associates reported on their experience with a randomized, placebo-controlled, double-blind study involving leuprolide acetate before myomectomy.[2] They stratified patients by uterine volume measured by ultrasonography and showed a significant decrease in intraoperative blood loss only in the patients with ultrasonographic volumes >600 ml.

The design of this study does not include placebo controls but does include a group of untreated patients (group A). Group B, the treated group, includes patients receiving a GnRH agonist, leuprolide acetate, by one of two routes. The groups were not evaluated over the same time period and did not have the same number of clinical or ultrasonographic studies before surgery. The patients, the ultrasonographer, and the surgeon were not blinded, so that an element of bias cannot be eliminated. This study could have been strengthened by incorporating blinding or placebo procedures.

The primary thesis cannot be tested because all patients in group B were randomized not to determine whether they were candidates for vaginal or abdominal hysterectomy *before* therapy but, rather receive therapy regardless of uterine size. Reference to Table II shows that in group B uterine size varied from *12* to 18 weeks' gestational size. The authors have pointed out in the Material and methods section that all patients with uterine size ≤14 weeks' gestational size were considered candidates for vaginal hysterectomy; therefore we should conclude that at least one patient (if not more) in group B had uterine size ≤14 weeks' size before therapy and that preoperative therapy made no difference in qualifying those patients for vaginal hysterectomy as a result of uterine size only. Similarly, in group A (the untreated patients) the mean uterine size was 14.4 weeks, yet only 4 of 25 patients underwent vaginal hysterectomy. The authors provide us with no standard deviations or measures of variance; consequently, it is not possible to determine how many patients in each group should have qualified for vaginal hysterectomy as a result of initial uterine size. Nor is it possible to determine if Student's t test is appropriate for assessing significance.

To make meaningful comments about the blood loss in surgery, hospital stay, and period of convalescence in relation to the use of agonist therapy, it may be more appropriate to stratify the comparison between untreated and treated groups by the route of the hysterectomy. It is possible that agonist therapy could improve these end points irrespective of the route of surgery, but we are unable to assess this possibility with the data presented. No information correlating clinical estimates of uterine size, ultrasonographic volume determination of uterine size, and uterine weights in individual patients was provided. Such information might help us evaluate the role of these variables in clinical decision-making. I hope the authors will include their observations in a final manuscript.

A reasonable question is, what do ultrasonographically determined uterine volumes mean? In both groups A and B the uterine weights were approximately 45% of the uterine volume. Does that mean that the uterus has a density one half that of water? Using Archimedes' principle, we recently measured the volume of water displaced by extirpated uteri from 10 different patients and found that the true uterine volume closely approximates the weight of the uterus in grams. In an animal study a group of Japanese investigators determined ultrasonographic volume of the canine prostate and subsequently compared the ultrasonographic determinations with specific gravity, actual volume, and measured weights of the canine prostates determined after prostatectomy. They showed the specific gravity of the canine prostate to be approximately 1.06 and that an accurate weight could be determined by multiplying volume by specific gravity.[3]

Ultrasonographic evaluation of the pelvis may help to assess adnexal structures; however, I can find no evidence in this study or elsewhere that uterine volume measured by ultrasonography can be translated into estimates of uterine weight or gestational size. It is likely that the irregular contours of some uteri do not correspond to any single geometric formula for volume determination; therefore use of a single formula should produce an overestimation of true uterine volume, particularly in women with leiomyomas.

The authors concluded that preoperative therapy with GnRH agonist "allows selected patients *safely* to undergo vaginal hysterectomy." In group B 9% of patients who had vaginal hysterectomy attempted required abdominal completion of the surgery. In several large series approximately 1% of patients who had vaginal hysterectomy attempted required abdominal completion.[4] The current report suggests that the authors' incidence of failed vaginal hysterectomy is a significant problem that could outweigh any benefits that may be ascribed to GnRH agonist therapy.

In summary, the addition of placebo controls and the use of blinded observations would have provided meaningful data regarding the possible effects of preoperative GnRH agonist therapy. In addition, the correlation of clinical examination, ultrasonographic volume determination, and uterine weights in individual patients might have provided valuable information for the clinician who is trying to determine which patient with leiomyomas is a candidate for vaginal hysterectomy.

DR. PEDRO A. POMA, Melrose Park, Illinois. I want to state my bias. I prefer vaginal hysterectomy if possible. If the authors are going to continue with their studies, I would like them to consider a group in whom progestin could be used. On many occasions, using progestin, which is probably one-tenth of the cost of this other fancy new product, would produce the same results.

DR. DAVID V. FOLEY, Wauwautosa, Wisconsin. I stand, not to comment on this article, although I thought it was a very meaningful one, but to challenge academicians to get back to teaching vaginal surgery.

I have been privileged over the last 14 years to be a board examiner and have been agonized by the lack of vaginal surgery that has been taught to and done by the candidates. At the last examination I examined 20 candidates. In their entire case list there were two vaginal hysterectomy cases. I asked each one of these candidates what he or she would do with a traumatic cystotomy, and not one of them could handle the situation independently.

I think that this is a travesty, and I think that we should get back to doing pelvic surgery and teaching pelvic surgery.

DR. ROBERT K. ZURAWIN, Houston, Texas. I guess that (Dr. Foley's comment) stole a little bit of the thunder from what I was going to say. The authors mentioned that in the treatment study 16 of the 19 patients who underwent hysterectomy required morcellation. That also indicates that a thorough knowledge of vaginal operative technique is necessary. When I was taught vaginal surgery, the decision to perform a hysterectomy abdominally as opposed to vaginally had to do with your clinical judgment. In other words, the success of a vaginal hysterectomy had to do with the proper selection of patients.

I did not hear any mention of whether the gravidity of the patient affected selection, nor was there any mention of pelvic anatomy, such as the narrowness of the arch, the width of the ischial spines, or those things that might also influence a surgeon to attempt a hysterectomy vaginally. But, as the previous questioners mentioned, I think that if you're going to embark on a hysterectomy with a uterus of this size, especially those that either before or after treatment are going to require morcellation, you're going to need a certain amount of surgical skill that medical treatment is not going to affect one way or the other.

DR. STOVALL (Closing). As most of you are probably aware, the United States Food and Drug Administration is currently requiring all agonist manufacturers to perform blinded placebo-controlled trials to determine the efficacy of preoperative GnRH agonist prior to myomectomy or hysterectomy. We are currently involved in three such trials, and we believe that these additional data will confirm the data presented today. It is very difficult, however, when doing clinical trials with agonists to do placebo-controlled, blinded trials because of the effects of the agonists, such as uterine size reduction, the hypoestrogenic effects with hot flashes, and vaginal dryness. Thus it is nearly impossible to perform a truly "blinded" trial.

All patients in the groups initially had uteri that were ≥14 weeks' size. The size was confirmed before treatment or surgery by two examiners. To calculate uterine volume ultrasonographically, we used the formulas that have been shown in the past to correlate gestational size with uterine volume; this was done by Sauer et al.[1] and others from several institutions.

Progestins, danazol, and other agents have been used in an attempt to reduce uterine size, but these have not been nearly as successful as GnRH agonists, or they have not been successful at all.

This study was also done in an attempt to increase the number of vaginal hysterectomy candidates at our institution so that our residents would have increased training in vaginal surgery. As the number of general gynecology patients decreases and as the indications for hysterectomy decline, we have been faced with a decrease in the number of surgical candidates for resident training, as have other institutions. An outgrowth of this has been to increase the number of vaginal hysterectomies that our residents perform.

To attempt vaginal hysterectomy for large uteri, you must be comfortable with pelvic anatomy, uterine morcellation, and other techniques used to remove large uteri. I think that more than that, you must be persistent in what you are doing and must have good operative assistance.

We believe that there are probably three roles for GnRH agonist therapy for myomas. The first is for patients who have a low preoperative hematocrit, to increase the hemoglobin and hematocrit before an intended operative procedure and thereby to decrease the chance that the patient will require either intraoperative or postoperative blood transfusions. Second, we believe that selected patients can undergo conversion from abdominal hysterectomy to vaginal hysterectomy, which decreases their overall operative and postoperative morbidity. Finally, there are patients who will undergo myomectomy who might benefit from preoperative GnRH agonist therapy. Although these patients have not been clearly identified in the literature, certainly patients who have very large uteri probably do benefit from GnRH agonist therapy before myomectomy.

Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies?

Emanuel P. Gaziano, MD, G. Eric Knox, MD, Richard P. Bendel, MD, Steven Calvin, MD, and Deb Brandt, RDMS
Minneapolis, Minnesota

Few studies have addressed the significance of umbilical artery pulsed Doppler velocimetry in multiple gestation. Level II ultrasonography and pulsed Doppler studies were performed in 94 twin pairs and seven sets of triplets, which yielded data on 207 fetuses. A systolic/diastolic ratio was calculated for each fetus; abnormal pulsed Doppler velocimetry showed high correlation with adverse pregnancy events. Those with abnormal Doppler findings tended to be born 3 to 4 weeks earlier and to exhibit a greater number of stillbirths and structural malformations, as well as greater morbidity, when compared with fetuses without abnormal Doppler results. Fifteen of 17 infants with abnormal antenatal waveforms suffered serious morbidity. Seven were small for gestational age, and two were borderline for small for gestational age. An additional five infants with abnormal waveforms were appropriate for gestational age but were either recipient or donor in the twin transfusion syndrome. Eleven fetuses with this syndrome are described. Donor twins tended to be severely small for gestational age, with 7 of the 11 infants showing elevated systolic/diastolic ratios. Amniotic fluid volume tended to be diminished in the donor's sac but normal or increased in the recipient's sac. The observations in the study correlate with suspected physiologic changes of this syndrome. Because present findings suggest that fetuses with abnormal velocimetry suffer increased morbidity and mortality, a more rational method of management that uses Doppler data is suggested for multiple gestations. (AM J OBSTET GYNECOL 1991;164:1426-33.)

Key words: Doppler, ultrasonographic diagnosis, twins, twin transfusion syndrome, abnormalities, pregnancy

Elevated resistance in the umbilical artery as evidenced by an increased systolic/diastolic ratio has been associated with retarded fetal growth and certain fetal anomalies.[1-7] In twin gestations a large number of infants who are small for gestational age (SGA) at birth have abnormal umbilical artery Doppler findings.[8,9] Although recent information suggests that pulsed Doppler data might be of benefit in the management of twin pregnancies, the dynamic fetal cardiovascular changes associated with twin transfusion syndrome pose certain unresolved problems.[10,11] For example, Giles et al.[8] report that a number of SGA twins with twin transfusion syndrome demonstrate no intertwin difference in antenatal Doppler ratios. Pretorius et al.[11] suggest that Doppler studies in the twin transfusion syndrome did not differentiate between donor and recipient fetus in this syndrome or provide prognostic data for outcome. In a comparison of singleton pregnancies, Farmakides et al.[9] report a small increase in systolic/diastolic ratios for normal twin pregnancies and slightly lower systolic/diastolic ratios in twin fetuses with retarded growth. Therefore the relationship between abnormal Doppler values and neonatal outcomes in multiple gestations continues to demonstrate several unresolved issues.

In an effort to assess the significance of abnormal pulsed Doppler measurements in multiple gestations, an analysis is made of the umbilical artery Doppler findings, fetal ultrasonographic characteristics, and neonatal outcomes in a group of infants from such pregnancies. As a result of these findings, a potential role for pulsed Doppler velocimetry is described for multiple gestations.

Material and methods

From Jan. 1, 1987, to Jan. 4, 1989, 207 fetuses from multiple gestation pregnancies underwent analysis of pulsed Doppler waveform recordings from the umbilical artery, as well as complete level II ultrasonographic examinations. The study population consisted of high-risk patients with multiple gestations who were referred for level II ultrasonography to the Abbott-Northwestern Perinatal Center, a tertiary site. The sample included 94 twin pairs and 7 sets of triplets. Two fetuses were excluded from the sample because complete ultrasonographic data were not available. There-

Table I. Relationship between antenatal umbilical artery systolic/diastolic ratio and principal outcome variables

	Umbilical artery ratio		
	Normal systolic/diastolic ratio	*Abnormal systolic/diastolic ratio*	*p Value*
Total (N = 207)	190 (92%)	17 (8%)	
Gestational age (wk) at time of study	28.6	27.7	NS
Gestational age (wk) at delivery	33.9	30.4	0.001
Birth weight <1500 gm	19%	77%	0.001
Structural malformations	1%	12%	0.002
Apgar score ≤6 at 5 min (live-born)	8%	24%	0.018
Stillbirths	3%	12%	0.02

fore data were compiled on 207 fetuses. During the study period, 377 separate Doppler recordings and detailed ultrasonographic measurements of these pregnancies were taken. Pulsed Doppler recordings were obtained from a midsegment of fetal umbilical artery with an ATL Ultramark 8 with either a 3 or 5 MHz transducer and a sample volume size of 1.5 mm^2. Each fetus of the multiple gestation pregnancy was considered separately; the individual sac, fetus, and respective umbilical cord were identified by real-time ultrasonography. Three to five reproducible waveforms were analyzed, and a systolic/diastolic ratio was calculated; peak systolic/diastolic values were measured by calipers. Doppler values were not used for patient management decisions. For purposes of analysis only the last measurements taken before delivery were considered.

Abnormal Doppler values were assigned by comparing the value obtained in the study group with values from a normal group of 274 patients with singleton gestations matched for gestational age. Maximum and minimum normal values for systolic/diastolic ratios were etablished for each gestational age. The maximum systolic/diastolic ratios ranged from 5.0 at 16 weeks to 3.0 at 39 weeks; minimum systolic/diastolic ratio values obtained were 2.8 for 16 weeks to 2.1 at 39 weeks.

Amniotic fluid volume was considered to be increased if the greatest vertical pocket measured ≥10 cm and was considered to be decreased if the greatest vertical pocket measured ≤2 cm.

Neonatal outcome parameters included gestational age at the time of level II ultrasonography, gestational age at delivery, distribution of birth weights, presence and type of structural malformations, stillbirth, Apgar score, and delivery route. SGA infants were defined as those with a birth weight ≤10th percentile, according to Battaglia and Lubchenco.[12] Finally, the outcomes of all 16 SGA infants from the study population, as well as those of all 17 infants with abnormal Doppler values, were tabulated.

Newborns from pregnancies with twin transfusion syndrome were identified by neonatal assessment, including examination of the placenta. Newborns were then determined to be either the donor twin or the recipient twin in the syndrome; classification depended in part on the relative degree of anemia or polycythemia observed. Neonatal data used to confirm twin transfusion syndrome included disparity of newborn weight, neonatal hemoglobin and hematocrit, and microscopic examination of the placenta demonstrating a monochorionic placenta. Major neonatal morbidity, such as respiratory distress syndrome, intraventricular hemorrhage, bronchopulmonary dysplasia, fetal anomalies, and transient tachypnea of the newborn, was recorded.

The above data were tabulated and analyzed according to relationships with the umbilical artery systolic/diastolic ratio for each fetus studied. Means were calculated for the variables or groups of variables tested. Where appropriate, t tests, medians, standard deviations, and χ^2 values were calculated and compared.

Results

Table I indicates the relationship between umbilical artery systolic/diastolic ratios in multiple gestation pregnancies and principal outcome variables. Gestational age at the time of level II performance was not different between those with normal and those with abnormal systolic/diastolic ratios. However, those fetuses with abnormal systolic/diastolic ratios were born approximately 3 weeks earlier than were those with normal ratios (p = 0.001). In addition, 13 of 17 fetuses (77%) with abnormal systolic/diastolic ratios were delivered with birth weights <1500 gm, compared with 19% with similar birth weights in the normal ratio group. Structural malformations occurred in 12% of the abnormal ratio group and in only 1% of the normal ratio group. Similarly, a greater proportion of infants with abnormal antepartum ratios had a low 5-minute Apgar score, and route of delivery demonstrated no difference between systolic/diastolic ratio groups.

Sixteen of 207 fetuses (8%) were SGA at birth; Table II is a summary of Doppler findings and outcomes in each. Six cases represented twin transfusion syn-

tended to be profound in the donor twin. Three of the donor twins were stillborn, and the rest suffered significant neonatal morbidity. All except two of the infants had one or more abnormalities of amniotic fluid volume, pulsed Doppler values, or ultrasonographically estimated fetal weight at ≤35th percentile. In both cases these twins were born uneventfully at 37 and 38 weeks, respectively, at a level I hospital.

Table III illustrates the outcomes in the 10 fetuses who showed abnormal pulsed Doppler findings antenatally but were not SGA. Two were between the 10th and 20th percentiles for birth weight and missed the SGA classification by only 150 gm. Five were appropriate-for-gestational-age (AGA) fetuses (three donor and two recipient twins) involved in the twin transfusion syndrome. One exhibited major congenital anomalies, including gastroschisis and ventricular septal defect, and one twin was opposite a sibling with anencephaly (both showing elevated systolic/diastolic ratios). Finally, one twin had a borderline elevated ratio of 4.4 at 34 weeks; he was appropriate-for-gestational-age without apparent morbidity. With the exception of that infant, all remaining AGA twins with abnormal ratios were admitted to the neonatal intensive care unit; the recipient twin in the twin transfusion syndrome suffered serious morbidity.

Amniotic fluid volume tended to be increased or to show hydramnios in 16% of the multiple gestation sample. This relationship held for those grouped according to umbilical artery ratio and birth weight status (SGA vs non-SGA) at p values of 0.01 and 0.06, respectively. Amniotic fluid volume tended to be decreased in the donor twin and increased in the recipient twin, as noted.

Comment

The numbers of patients in this study and their attendant complications permit sufficient opportunity to infer the potential role of pulsed Doppler velocimetry and real-time ultrasonography in the management of such pregnancies.

This article suggests that patients with abnormal Doppler findings have a significant number of other adverse pregnancy complications, some of which are unique to multiple gestations. Of the 17 abnormal Doppler systolic/diastolic ratios in the study group, 7 were associated with an SGA infant. Of the remaining 10, all infants except two were admitted to the neonatal intensive care unit. Five AGA infants (three donor and two recipient fetuses) were products of pregnancies complicated by twin transfusion syndrome. All members of this group either died in the neonatal period or had prolonged, complicated neonatal courses. Of the remaining five, two were borderline SGA, with birth weights ≤20th percentile, and one was affected with gastroschisis and ventricular septal defect. Thus 15 of 17 fetuses with abnormal Doppler velocimetry had adverse perinatal outcomes.

In addition, those fetuses with abnormal Doppler systolic/diastolic ratios were born 3 to 4 weeks earlier ($p = 0.001$) than those fetuses with normal ratios. Fetuses with abnormal waveforms were much more likely to have structural malformations (12% vs 1%), to be <1500 gm in weight, to have lower 5-minute Apgar scores, and to suffer intrauterine fetal death (12% vs 3%).

Several investigators suggest that Doppler studies may be useful in evaluating retarded fetal growth in twin pregnancies. Farmakides et al.[9] reported slightly lower systolic/diastolic ratios in growth-retarded twins when compared with singletons. Although our study did not specifically address this issue, review of Table II indicates that numerous SGA twins exhibited markedly abnormal waveforms, including reversal of diastolic flow.

The present investigation demonstrates experience with 11 fetuses with documented twin transfusion syndrome. Giles et al.[8] reported in their article on twin pregnancies, "We believe that twin-to-twin transfusion may be strongly suspected if a discrepancy in ultrasound size is seen in the presence of no A/B (S/D) ratio difference." Our article does not support this position. Although both recipient and donor twins may have normal velocimetry, the most consistent observations indicate that the donor (usually an SGA fetus) will show abnormal systolic/diastolic ratios, as did 7 of 11 donor fetuses. Normal systolic/diastolic ratios were most frequently seen in the recipient twin, although abnormal ratios were noted in 2 of 10 recipient fetuses. These observations agree with those of Pretorius et al.,[11] who noted varying Doppler findings in both donor and recipient fetuses in the twin transfusion syndrome. Commonly, the donor fetus showed normal or decreased amniotic fluid volume, whereas the recipient fetus indicated signs of both hydrops and hydramnios.

Unbalanced arteriovenous shunting appears to be the major physiologic event in the twin transfusion syndrome. The donor twin becomes progressively anemic and hypovolemic and experiences a consequent decrease in umbilical blood flow. The resultant increase in umbilical vascular resistance accounts for the present observations, which were noted predominantly in donor twins of increased systolic/diastolic ratios; this reflects increased resistance to flow. Oliguria was a clinical problem for the neonatologists in many of the profoundly SGA donor twins, and decreased amniotic fluid volume was a frequent observation; both of these support the hypothesis for the previously described sequence of events. Our findings, which are in agreement with those of Pretorius et al.,[11] support the concept that twin transfusion syndrome is a complex pathophysiologic event. However, Doppler interrogation of the umbilical artery also may permit study of the spectrum of change and severity in this altered hemodynamic state.

The role of real-time ultrasonography in the management of multiple gestation pregnancy recently has received increased attention. D'Alton and Mercer[13] indicate that significant reductions are possible in preterm delivery rates and in the incidence of perinatal deaths when real-time ultrasonography is used systematically as an adjuvant to routine prenatal care.

Our data suggest that fetuses from multiple gestations with abnormal umbilical artery systolic/diastolic ratios suffer a disproportionate increase in serious short- and long-term neonatal morbidity. For singleton pregnancies, both Berkowitz et al.[6] and Rochelson et al.[7] reported that abnormal umbilical artery velocimetry is valuable in identifying fetuses at risk for adverse perinatal outcomes. Our data also suggest a potential role for pulsed Doppler fetal velocimetry when combined with other real-time ultrasonographic measurements in the clinical management of multiple gestations.

Because morbidity and mortality occurred principally in the 8% of multiple gestation pregnancies with abnormal Doppler values, Doppler screening and real-time measurements (performed at 24 to 26 weeks' gestation, for example) could be used to identify those pregnancies most at risk for adverse outcomes. Those pregnancies showing concordant fetal growth and normal Doppler values would require less frequent ultrasonographic examinations and tests of fetal well-being. Fetuses demonstrating abnormal velocimetry could be placed in a program of more intense fetal surveillance. Thus perinatal resources could best be directed to the small number of fetuses at risk for significant morbidity and could reduce the frequency of testing for the lower-risk group. Future clinical studies are needed to assess the validity of these observations and to originate a specific program of testing and follow-up that is based on the results of Doppler data.

Discussion

DR. PAUL G. TOMICH, Maywood, Illinois. Dr. Gaziano has investigated the usefulness of Doppler velocimetry in the management of multiple pregnancies. Two hundred seven fetuses (94 twin pairs and 7 sets of triplets) were studied. There were 190 normal studies and 17 abnormal studies. The results of these studies were not used for patient management. Neonatal outcome parameters were tabulated and analyzed and the data provided give us the "natural history" of those infants with abnormal Doppler results. Those 17 fetuses were statistically at increased risk for adverse perinatal outcome, including earlier birth, birth weight <1500 gm, major anomaly, low Apgar score, and stillbirth. Fifteen of the 17 fetuses had significant perinatal morbidity.

Much of the prenatal surveillance activity in twin pregnancies is driven by the concept of discordance, which was popularized by Babson[1] in 1964. With growth disparity, the differential diagnosis includes intrauterine growth retardation and the twin-twin transfusion syndrome. In the past obstetricians did not have a useful tool with which to screen twin pregnancies for adverse outcome; they relied on serial ultrasonographic examinations to assess potential fetal problems. Doppler ultrasonography, which was introduced as a clinical tool in the mid-1980s, would seem to be the ideal surveillance tool for multiple pregnancies.

Five previous studies have investigated the role of Doppler studies in the management of twin pregnancies.[2-6] Four of these studies have demonstrated good sensitivity (76%), specificity (83%), and positive predictive value (77%) for detecting delayed or adverse outcome. The study of Hastie et al.,[6] with a strict definition of SGA, had a sensitivity of 29%, a specificity of 88%, and a positive predictive value of 34%.

The value of velocimetry in the diagnosis of the twin-twin transfusion syndrome has not yet been established. Farmakides et al.[2] suspected twin-twin transfusion syndrome when growth discordancy or significant systolic/diastolic differences occurred. Pretorius et al.[7] reported variable Doppler findings in twin pregnancies with the twin-twin transfusion syndrome. Dr. Gaziano has identified six pregnancies with twin-twin transfusion syndrome. Four of the six donors had elevated systolic/diastolic ratios. Five of the recipient twins had normal systolic/diastolic ratios.

Gaziano and colleagues suggested that Doppler screening at 24 to 26 weeks' gestation would detect those twin pregnancies at high risk for adverse perinatal outcome, so that a more intensive fetal surveillance program could be initiated to improve outcome.

In my opinion, pulsed Doppler velocimetry is still in the investigational stage for the management of twin pregnancies. Further clinical studies are necessary before its use is considered as "standard of care" for twin pregnancies.

I have the following questions for Dr. Gaziano: (1) As a result of this study, what is your current management plan for patients with multiple pregnancies? (2) If a patient has an abnormal Doppler study, how is her management altered? (3) How are you managing patients who have ultrasonographic or Doppler studies that are suggestive of or diagnostic of the twin-twin transfusion syndrome? Are you doing percutaneous umbilical blood sampling?

DR. NEIL K. KOCHENOUR, Salt Lake City, Utah. Doppler velocimetry is a recently developed addition to the armamentarium for antepartum fetal assessment. A number of investigators have demonstrated that an abnormal waveform is indicative of a poor perinatal outcome. General agreement exists that the chances of having a jeopardized fetus are increased in the presence of an abnormal waveform. The important question is, is this clinically useful and, if so, when and in what patient populations?

In this article the authors adopted the Doppler waveform as a method of evaluating twin gestations and asked the question, is pulsed Doppler velocimetry useful in the management of multiple gestation pregnancies? Unfortunately, I do not believe that these authors answered their own question. Here, as in the vast majority of literature concerning Doppler velocimetry, a poor outcome is correlated with the presence of an abnormal waveform. The authors demonstrated that fetuses with abnormal Doppler findings tend to be born early, to have a greater number of stillbirths and structural malformations, and to have greater morbidity than do those fetuses with normal waveforms. They did not show that this form of evaluation is helpful in improving the management of patients with twin gestations. For the purposes of their article they used only the measurement taken closest to delivery. I am interested in knowing whether changes occurred in the Doppler flow pattern in patients with serial follow-up. If so, did normal values change to abnormal ones, or did abnormal values change to normal?

Because the authors used only one value in their analysis, are they advocating the use of Doppler as a one-time screening tool or are they advocating its use for serial evaluation? If they advocate a one-time use, when should this be done? They suggest 24 to 26 weeks' gestation, but I do not see any evidence to support this interval. In fact, the mean gestational age at the time of the Doppler evaluation in this series was 28 weeks.

I have a particular interest in the twin-twin transfusion syndrome. The existing literature on this topic regarding umbilical artery Doppler velocimetry is inconclusive. These authors do not support the findings of Giles et al.,[1] who found that a discrepancy in ultrasonographically estimated fetal weight in the presence of no fetal systolic/diastolic ratio difference was indicative of fetal transfusion. Pretorius et al.[2] found an intertwin difference of 0.4 in all eight cases of twin-twin transfusion. In at least three patients with twin-twin transfusion in this series, the systolic/diastolic ratio difference was <0.4. This study found abnormal systolic/diastolic ratios in 7 of 11 donor fetuses and normal systolic/diastolic ratios in the majority of recipient twins. How do the authors recommend using Doppler to diagnose the twin-twin transfusion syndrome, and how did they differentiate this syndrome from other causes of discordant growth? The authors state that the diagnosis was made by neonatal assessment, including examination of the placenta. What were the criteria for this diagnosis?

The authors state that 77% of the fetuses with an abnormal systolic/diastolic ratio were born with a birth weight of <1500 gm, compared with 19% of the normal ratio group. Because those with abnormal Doppler results were also born 3 weeks early, I believe that these data should be normalized for gestational age.

The authors report that a greater proportion of infants with abnormal antepartum ratios exhibited low 5-minute Apgar scores. What is the significance of an Apgar score when the average age at birth was 30 weeks for the abnormal infants and 33 weeks for the normal infants? Were there differences in cord blood gases?

The authors state that all of the 16 SGA fetuses but two had abnormalities of amniotic fluid volume or pulsed Doppler ratio or an ultrasonographically estimated fetal weight of <35th percentile. What is the significance of the 35th percentile, and why was it chosen? Are the authors suggesting that twins with an estimated fetal weight of <35th percentile are growth-retarded? Is Doppler velocimetry a better predictor of the SGA fetus than ultrasonographically estimated fetal weight? Were the structural abnormalities in the fetuses with abnormal waveforms ascertained with ultrasonography? If so, what was the value of the abnormal Doppler results in these fetuses? The authors state that in their study morbidity and mortality occurred principally in the 8% of multiple gestations with abnormal Doppler values. They conclude that this may identify those pregnancies that are at higher risk for adverse outcomes. I do not dispute this. However, how is the Doppler velocimetry used when a risk is identified? Is Doppler velocimetry better than existing methods of antepartum assessment for multiple gestations?

In summary, I believe that these authors have confirmed the findings of others. An abnormal waveform is associated with a poor perinatal outcome. However, they have not, to my satisfaction, demonstrated that the use of Doppler velocimetry improves the pregnancy outcome, which is, after all, the purpose of antepartum fetal assessment.

Dr. David B. Schwartz, Detroit, Michigan. I enjoyed the article. We have a particular interest in multiple pregnancies and have a specific multiple pregnancy program at our hospital. Most of my questions have been asked by the discussants, but I have two additional questions for Dr. Gaziano. I was unclear whether other fetal resistance and flow parameters were examined. If they were, was "centralization" of fetal circulation, such as the increased cerebral velocity or the decreased resistance that may be expected to occur with uteroplacental insufficiency, of help?

Second, I was unclear about the discordancy criteria that were used in the regular ultrasonographic examinations. Did the discordancy results correlate with the Doppler data, and would they have been of equal predictive value in these cases?

Dr. Gaziano (Closing). I appreciate the comments, and I'll try to address them in order.

First, I think it's very important that this presentation be viewed as one in which morbidity was sufficiently observed in multiple gestations with abnormal Doppler results and that this morbidity might serve in the future as a predictor or be useful in management.

In no way should you walk away from this presentation believing that Doppler velocimetry is the answer to the management of twin gestation for morbidity or mortality. I believe that Doppler velocimetry provides another piece of useful information, but we'll go through some of the specifics.

Do we routinely do Doppler examinations? Doppler examinations are part of our level II ultrasonographic examinations. We presently look at the Doppler values, but they are not the final decision-making factors for us. If we see an extremely abnormal Doppler value, such as reversal of diastolic flow, we may act on that information. We do not do cordocentesis for twin gestation.

The 24- to 26-week gestational age was used to create a hypothesis for future studies and was based on the possibility that intervention or changes in management might be effective at that gestational age.

With respect to the twin-to-twin transfusion observations in the literature, first of all, the study by Giles et al. was done with continuous-wave Doppler, and our study was done with pulsed Doppler. Continuous-wave Doppler is a blind approach. This article, and also the work by Pretorius et al., disagreed with the initial observation in the study by Giles et al., which is that there were no differences in Doppler in the twin-to-twin transfusion syndrome.

We did not obtain cord gas values. The significance for Apgar scores is simply another observation, in that overall morbidity was increased in the group with abnormal Doppler values.

Structural malformations were diagnosed antenatally by level II ultrasonographic examinations.

There were several questions related to the relationship between Doppler as a predictor of SGA babies and Doppler as a factor in predicting morbidity and mortality.

From similar data we have demonstrated that Doppler is no better than estimated fetal weight in the prediction of the SGA baby, but the point of this article is that if the Doppler value is abnormal, morbidity and mortality appear to be increased. The SGA fetus with normal Doppler values tends to have better outcomes compared with the SGA fetus with abnormal values (see Table II). For skeptics it is such observations that may confirm Doppler's unique management role.

Again, finally, let me conclude by saying that the purpose of the article was not to present strict guidelines regarding management but to suggest that the findings are significant enough to warrant prospective studies. Our belief, based on the present data, is that pulsed Doppler technology will be a useful management tool.

Bound volumes available to subscribers

Bound volumes of the American Journal of Obstetrics and Gynecology are available to subscribers (only) for the 1991 issues from the Publisher, at a cost of $61.00 for domestic, $88.27 for Canada, and $84.00 for international for Vol. 164 (January-June) and Vol. 165 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the Journal name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular Journal subscription.

Comparative efficacy of umbilical arterial Doppler indices for predicting adverse perinatal outcome

Dev Maulik, MD, PhD, Prasad Yarlagadda, PhD, James P. Youngblood, MD, and Pamela Ciston, RDMS
Kansas City, Missouri

A variety of descriptor indices for the umbilical arterial Doppler waveform are currently in use for predicting perinatal outcome. However, there is a paucity of data regarding the relative diagnostic merits of these indices. We addressed this issue in a prospective, blind study in which the diagnostic efficacy of the following Doppler indices was compared: resistance index, systolic/diastolic ratio, pulsatility index, and diastolic average ratio. The analytic technique consisted of the receiver operating characteristic method, which evaluates a test's ability to discriminate a diseased from a healthy population. The patient population consisted of 350 pregnant patients with gestational ages of 34 to 36 weeks. A continuous-wave Doppler device with a 4 MHz transducer was used to investigate the umbilical vessels. The test was performed only once in each patient. The abnormal outcome parameters included small for gestational age (<10th percentile), Apgar score <7 at 5 minutes, fetal distress (late and severe variable decelerations, absent variability, fetal scalp pH <7.20), umbilical cord arterial pH <7.10, presence of thick meconium, and admission to neonatal intensive care unit (>48 hours). The results showed that the resistance index had the best discriminatory ability when compared with other Doppler indices: the systolic/diastolic ratio ($p < 0.05$), the pulsatility index ($p < 0.001$), and the diastolic/average ratio ($p < 0.05$). It is concluded that of the various Doppler indices assessed in this investigation, the resistance index offers the best diagnostic efficacy in predicting perinatal compromise. (AM J OBSTET GYNECOL 1991;164:1434-40.)

Key words: Doppler indices, comparison, perinatal outcome, receiver operating characteristic

As the Doppler frequency shifts in a circulation reflect the velocity of blood flow, the analysis of the Doppler waveform can yield information on the hemodynamic condition of a circulatory system.[1] A number of descriptor indices for the Doppler waveform have been developed for general vascular and fetal applications.[2-5] Although it has been demonstrated that changes in the umbilical arterial Doppler indices can be associated with various pregnancy complications and can be diagnostic of fetal compromise,[6-9] there have been few investigations examining the comparative efficacy of these indices. Moreover, most of the existing studies are based on threshold values derived from the test's distribution attributes. The limitations of this approach are well recognized.[10, 11] The technique of receiver operating characteristics analysis is free from these limitations, as it enables comprehensive evaluation of a test's inherent discriminatory power to separate the compromised from the healthy population.[11, 12] This analytic approach was used in a prospective blinded study, which was designed to assess the diagnostic efficacy of the umbilical arterial Doppler indices for predicting adverse perinatal outcome in an indigent population. Out of this project, we have previously reported analyses of the discriminatory powers of the umbilical arterial systolic/diastolic ratio[13] and resistance index.[14] This concluding article compares the diagnostic efficacy of the various Doppler indices, with the use of receiver operating characteristic analyses for evaluating two tests performed on the same population.[15]

Material and methods

Patient population. The patient population, as briefly described here, is the same as reported earlier.[13] A total of 350 pregnant women with gestational ages from 34 to 36 weeks participated in the study. Most were medically indigent and had a high preponderance of adverse perinatal outcome. The study was conducted with the approval of the institutional review board, and an informed consent was obtained from each patient. The perinatal outcome parameters are as follows: small for

gestational age (<10th percentile), Apgar score<7 at 5 minutes, umbilical arterial (cord) pH <7.10, fetal distress (late decelerations, severe variable decelerations, absent variability, fetal scalp pH <7.20), presence of thick meconium, and admission to the neonatal intensive care unit (>48 hours).

Doppler procedure. The technique of Doppler examination has been described earlier. It should be noted that the examination was performed only once on each patient. Four Doppler indices (Fig. 1) were used in this comparison: the systolic/diastolic ratio (also known as the A/B ratio),[2] the resistance index[5] the Gosling peak-to-peak pulsatility index,[3] and the normalized end-diastolic frequency shift, described as the diastolic/average ratio.[4]

Data analysis. Comprehensive receiver operating characteristic techniques were used for data analysis.[14] These included visual analysis of the receiver operating characteristic curve on the basis of the measured test values, and determination of the optimal cutoff point and determination of area under the curve by use of trapezoidal and curve-fitting methods. The latter included the binormal graph technique as described by Swets and Pickett[15] and the exponential receiver operating characteristic curve-fitting method of England.[16] In this study, performances of the various Doppler indices obtained from the same patient population were evaluated with the use of areas under the receiver operating characteristic curve derived from the above techniques that also estimated the areas un-

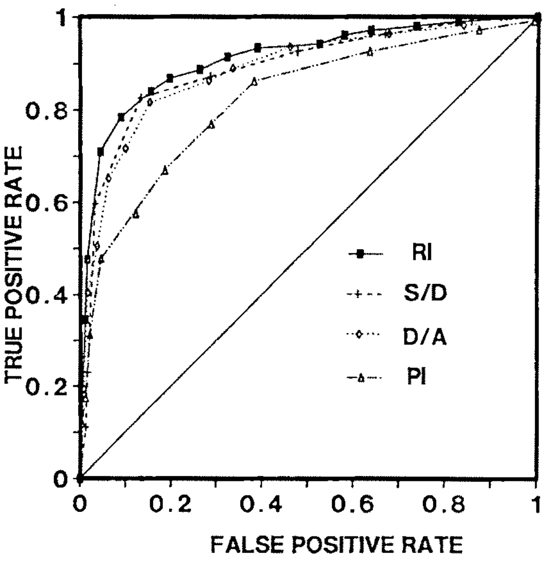

Fig. 2. Receiver operating characteristic curves of umbilical arterial Doppler indices. Data points are measured values of indices.

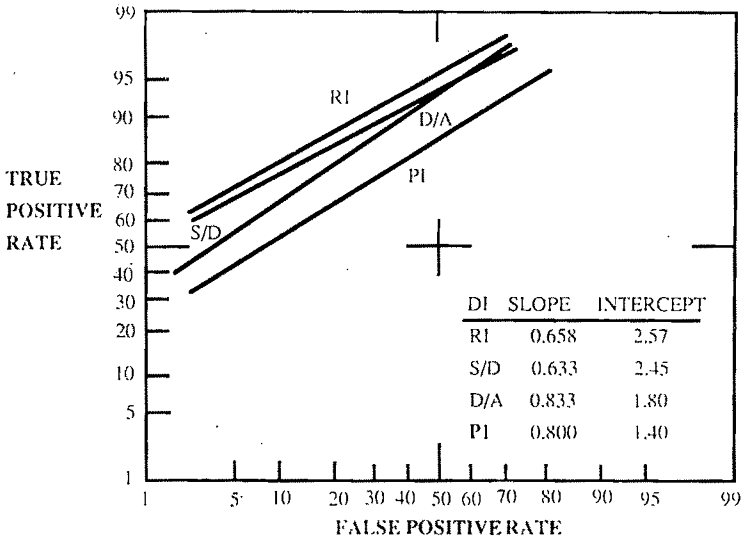

Fig. 3. Swets binormal receiver operating characteristic graphs of Doppler indices. Inset depicts slope.

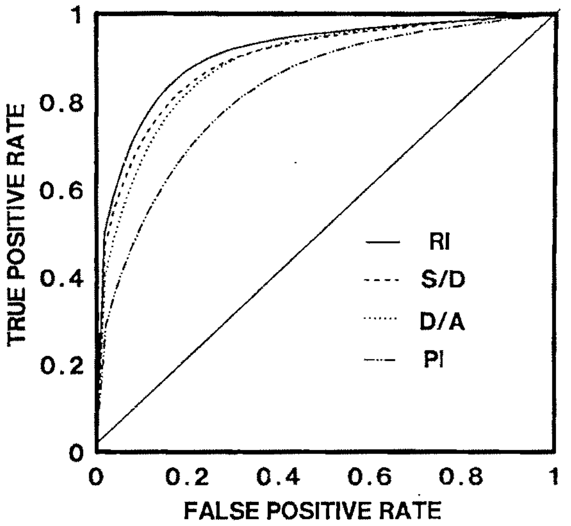

Fig. 4. Exponential receiver operating characteristic curves of umbilical arterial Doppler indices. Exponential *(E)* and receiver *(R)* values of indices were as follows: resistance index *(RI)*, E = 10.35; R = 0.629; systolic/diastolic ratio *(S/D)*, E = 8.621; R = 0.661; diastolic/average ratio *(D/A)*, E = 7.916; R = 0.555; pulsatility index *(PI)*, E = 4.797; R = 0.554.

der the curves and their standard errors. The method of Hanley and McNeil[17] was used for determining whether the differences in the areas under the curves of the four Doppler indices were random or real. The method essentially consisted of computing a ratio Z using the equation:

$$Z = (A_1 - A_2)/(SE_1^2 \times SE_2^2 - 2 \cdot r \cdot SE_1^2 \cdot SE_2^2)$$

where A_1 and A_2 are the areas obtained from the receiver operating characteristic curves from two indices, SE_1 and SE_2 are the corresponding standard errors, and r is the estimated correlation coefficient between A_1 and A_2. The latter was determined with Pearson product moment correlation, as the data in this study were of continuous scale.[18] The Z values were estimated for the various combinations of the indices, and the statistical significance (p values) was determined from the normal distribution table. The results were considered statistically significant if p was <0.05.

Results

The perinatal outcome data are presented in Table I. This is identical to our previously published report on the diagnostic efficacy of the systolic/diastolic ratio,[13] except for the cord arterial pH threshold, which was selected at 7.10. Fig. 2 depicts a visual comparison of the receiver operating characteristic curves based on the measured values of all the Doppler indices investigated in this study. As apparent, the resistance index and systolic/diastolic and diastolic/average ratios clustered closely and away from the pulsatility index. The latter was nearer to the diagonal line, indicating less inherent diagnostic efficacy than the other indices. Fig. 3 depicts the binormal receiver operating characteristic graphs of the Doppler indices as determined by the technique of Swets and Pickett.[15] It shows that the resistance index, systolic/diastolic ratio, and diastolic/average ratio cluster higher than the pulsatility index along the negative diagonal of the binormal graph, and the resistance index is located highest. The comparative exponential receiver operating characteristic curves of the Doppler indices are shown in Fig. 4. The estimated areas under the receiver operating characteristic curves and the corresponding standard errors derived by the various techniques are presented in Table II. As is evident, of all the indices the resistance index demonstrated the largest and the pulsatility index the least

receiver operating characteristic areas. Table III shows the statistical comparison of the receiver operating characteristic areas of the indices. The results demonstrate that the resistance index has the best discriminatory ability as compared with the systolic/diastolic ratio ($p < 0.05$), the diastolic/average ratio ($p < 0.05$), and the pulsatility index ($p < 0.001$). The systolic/diastolic ratio is superior to the pulsatility index ($p < 0.001$) but is not statistically better than the diastolic/average ratio ($p < 0.284$). Finally, it was observed that the performance of the diastolic/average ratio was statistically superior to the pulsatility index ($p < 0.006$).

Comment

Umbilical arterial Doppler indices show immense potential as a fetal surveillance tool. A number of indices have been described, but their relative merits or capabilities remain largely unsubstantiated. It may be argued that most of the indices express the pulsatility, which is the differential between the peak systolic and the end-diastolic values of the Doppler waveform; therefore there may not be any significant differences between their diagnostic efficacy. Indeed, all the indices demonstrate a high degree of correlation. However, there are computational differences in the indices that demonstrate varying distribution characteristics. The situation has been further complicated by the fact that various investigators have shown diverse preferences in choosing an index. Whereas some prefer the systolic/diastolic ratio, others continue to recommend the resistance index or the pulsatility index. Obviously, any choice must be based on the demonstrated diagnostic superiority of one index over the others.

Although such comparative efficacy can be investigated in terms of traditional test performance parameters of sensitivity, specificity, etc., these are dependent on the selection of distribution-related single threshold values. Limitations of such procedures have been recognized, especially since they do not take into account the overall performance of a test in discriminating between the diseased and the nondiseased population. To mitigate these deficiencies, the receiver operating characteristic–based analytic procedures have been recommended for evaluating a test.[18] These techniques have been used extensively in diagnostic radiology[11] and to a limited extent in evaluating the Doppler indices for fetal applications.[8, 13] Because of the differing clinical and technical circumstances, it may not be justifiable to recommend a specific test value as the universally applicable optimal operating point. As pointed out by Swets,[18] a fitted receiver operating characteristic curve, in contrast, represents all possible decision criteria as continuous data and is, therefore, independent of any single source of bias; the area under the receiver operating characteristic curve offers a general index of accuracy independent of other factors such as the population attributes or prevalence rates or the intended use of the test as a screening or a diagnostic tool.[11] Therefore the comparison of areas under receiver operating characteristic curves would allow reaching far more rational and convincing conclusions regarding diagnostic efficacy of tests than would be possible from a comparison of performances at a single operating point.

This analytic approach has been further extended to develop a method of statistical comparison of two tests performed in the same population.[18] In this study, the areas under the receiver operating characteristic curves of the various indices have been estimated by three methods. The rationale is as follows. The trapezoidal method is based on the measured receiver operating characteristic data points. However, this method underestimates the true area under the curve. Swets' graphic method of estimating the area under the receiver operating characteristic curve is considered to be the standard[11] and is most widely used. However, it approximates the receiver operating characteristic area, and, although it is considered to be a robust technique even when the distribution is not known,[17] it has an inherent assumption of Gaussian distribution of the test values.[15] Therefore application of this technique may not be appropriate for analyzing data such as the systolic/diastolic ratio and pulsatility index, which are known to have non-Gaussian distribution.[19] To ensure appropriateness of the analytic method, the receiver operating characteristic areas and standard error values were also estimated by the exponential model, which is free of any distribution assumptions about the underlying data. As evident, the results generated by Swets' graphic method are comparable to those obtained by the exponential receiver operating characteristic method confirming the applicability of the former, even when the data are known to be non-Gaussian in distribution.

Our results show discriminative differences between the various indices. Of all the indices, the resistance index demonstrated the largest and the pulsatility index the least receiver operating characteristic areas. Moreover, statistical analyses of the areas derived from the fitted curves and from the trapezoidal method show statistically significant superiority of the resistance index over the other indices. In contrast, the pulsatility index demonstrated the least diagnostic ability. The results of this study should be interpreted in the context of its practical implications. Although the diagnostic ability of the umbilical arterial Doppler indices in predicting fetal growth retardation has not been impressive,[13, 20] it has shown a significant potential in one area of fetal diagnoses. Several preliminary studies indicate that the technique, especially as applied to the umbilical arterial circulation, can be a powerful predictor of adverse perinatal outcome.[7, 8, 21] To assess further the utility of the Doppler technique as a fetal surveillance tool, it is important to standardize the technique. This includes selection of a descriptor index that would be computationally simple and yet diagnostically superior. Although the systolic/diastolic ratio has been used extensively in this country, its efficacy has not been compared with that of other indices. The resistance index enjoys the same degree of computational simplicity as the systolic/diastolic ratio, because both are based on the peak systolic and the end-diastolic values of the Doppler waveform. In contrast, the computation of pulsatility index and diastolic/average ratio is more complex and may be more prone to error, because it requires estimation of the area under the Doppler wave. To its advantage, the resistance index, unlike the systolic/diastolic ratio, demonstrates a statistically significant Gaussian distribution,[19] which facilitates its statistical manipulations. However, the most relevant point is the inherent discriminatory efficacy of the resistance index as a diagnostic test. Because of this, its use should be preferred for assessing umbilical arterial hemodynamics. Future studies will address the same issue in regard to repetitive testing in the antepartum period for predicting fetal compromise.

We acknowledge the invaluable assistance of John A. Swets, PhD, Cambridge, Massachusetts, in performing the binormal receiver operating characteristic analysis; we are also grateful to William England, PhD, Baltimore, Maryland, for his assistance in performing exponential analysis.

Discussion

Dr. Daniel A. Rightmire, Springfield, Illinois. This article is of great interest to all who follow the developments of obstetric Doppler, because each of us has our favorite Doppler index. Coming after the demonstration of the non-Gaussian characteristics of the systolic/diastolic ratio and the Gaussian distribution of the resistance index, this article presents the second strong, rational argument for the standardization of the reporting of obstetric Doppler data in the resistance index format. The exception would appear to be for those studies or cases in which diastolic Doppler frequency shifts are lost below the high-pass filter or are actually reversed.

I would like to ask Dr. Maulik a few questions. First, what have you determined to be the best threshold value of the resistance index in your study? Also, what statistical method did you use to find that optimum decision threshold?

Second, now that you have shown us the receiver operating characteristic curves, why should we not continue to use systolic/diastolic or diastolic/average threshold values, which are comparable to the best resistance index value for predicting poor pregnancy outcome? Surely the systolic/diastolic value of 3.0 that has been widely publicized as the threshold of abnormal waveforms in third-trimester umbilical artery studies seems to be as good a discriminator as any resistance index value.

I would like to point out that the receiver operating characteristic curves can be very different when different end points are used to describe abnormal pregnancy outcome. Thus the receiver operating characteristic curve for the prediction of fetal growth retardation is probably different from that used to predict operative delivery for fetal distress. This is demonstrated by the plots in Fig. 1, which are based on Gosling's pulsatility index data developed by Gudmundsson and Marsal.[1] It is conceivable that the discriminating ability of the various Doppler indices could be different for these different curves for different definitions of poor pregnancy outcome.

Perhaps, as Hanley[2] has suggested in a recent review, receiver operating characteristic curves could also be different depending on the types of patients and institutions in which the curve is developed and who the operators are. Thus Dr. Maulik may not have proved the general case that the resistance index will always be superior to the other Doppler indices.

Finally, I wish to thank Dr. Maulik for publicizing these new decision-making techniques. This method of analysis of receiver operating characteristic curves should be more widely applied to our diagnostic problems. They might help us decide whether competing tests, such as the nonstress test, contraction stress test, biophysical profile score, or other test of fetal wellness, or lack thereof, are to be preferred over the others. Indeed, receiver operating characteristic curve analysis may help us decide whether sequential testing schemes such as nonstress testing followed by contraction stress testing or biophysical profile scoring followed by contraction stress testing have any demonstrable advantage. Examples of similar applications have been introduced into our literature but appear to have received little recognition.[3, 4]

Dr. William J. Ott, St. Louis, Missouri. This article is an extension of a study presented at this association in 1989.[1] As such, the study suffers from the same minor weakness of the previous study. Receiver or relative operating characteristic curves is a statistical method that has only recently begun to be used in obstetric research. This method was first used in medical analysis to evaluate radiologic instrumentation to determine the ability of various systems to differentiate between signal and noise. The test was designed to evaluate situations where a clearcut yes or no (positive or negative) result was expected. The extension of this test to situations where less clear-cut end-points, such as the clinical parameters used in this study, may make this a somewhat less accurate technique. But as mentioned in the critique of last year's study, there are no clear clinical criteria (other than mortality) that can be used to evaluate clinical outcome.

The results of today's paper indicate that the resistance index and systolic-to-diastolic ratio are slightly superior than other, more complicated mathematic methods of quantifying umbilical arterial Doppler waveforms. It is not too surprising that these two techniques have very similar accuracies, since they are almost identical, simplified mathematic methods of quantifying Doppler waveforms.

Since Doppler blood flow studies are becoming widely used as a method of fetal evaluation, the authors are to be congratulated for presenting one of the first detailed comparisons of the accuracy of the various Doppler indices currently in use.

REFERENCE

DR. CHESTER B. MARTIN, JR., Madison, Wisconsin. Since the same terms appear in the systolic/diastolic ratio and resistance index, I wonder if it is a mathematic fluke that the two curves appear different. For each value of systolic/diastolic, a corresponding resistance index can be calculated mathematically, and the reverse. It appeared to me that you had more points on your resistance index graph than on the systolic/diastolic curve. If you had evaluated the two indices at the corresponding values, would they not have given identical results?

DR. MAULIK (Closing). I would like to express my sincere thanks to Drs. Rightmire and Ott for their critique of our article. I also thank Dr. Martin and the colleague from Chicago for their interest in our work. I shall try to respond to their comments and questions in an adequate manner within the time limit.

The optimal threshold value of the resistance index for diagnosing adverse perinatal outcome in our population is 0.66. We determined this by receiver operating characteristic analysis in which the optimal balance between the true-positive and false-positive rates were determined by graphical assessment of the receiver operating characteristic curve derived from the measured operating points of the test value. We presented this information at the Second Congress of the International Perinatal Doppler Society in Paris in 1989. Regarding the comment on the ability of the resistance index to assess the negative end-diastolic flow, it is well recognized that this index reaches the value of unity when the end-diastolic frequency shift becomes zero, indicating an absence of forward flow. Obviously, it will not reflect any further changes in the frequency shift in the negative direction. Only the pulsatility index is capable of reflecting the latter phenomenon. However, the latter occurrence is very rarely encountered in the umbilical arterial circulation and represents further deterioration in the condition of a fetus in dire distress. Recently a modification of the resistance index has been described by Prof. Pourcelot; I have had the privilege to validate this along with Profs. Arbeille and Pourcelot. We shall have the opportunity to present this study at the next annual meeting of the American Institute of Ultrasound in Medicine.

Regarding the continuing usage of the systolic/diastolic threshold value of 3.0, the receiver operating characteristic analysis conducted by our group indicated a general optimal point of 2.9. As the measurement error may contribute up to 10% of the variance, there may not be any pragmatic difference between these two values. We presented these data during the last Central Association meeting. Regarding the relative efficacy of the various Doppler indices, a comparison of the areas under the receiver operating characteristic curve of these indices offers a more rational and convincing approach than that based on the arbitrary selection of a single operating point of a test. Dr. Rightmire is quite correct in emphasizing that the discriminatory ability of the various indices is very much dependent on the differing definitions of the outcome criteria. We certainly do not intend to give the impression that our demonstration of the superiority of the resistance index holds true for all circumstances and population types. Indeed, the diagnostic efficacy of Doppler velocimetry should be tested, taking into account various outcomes with differing prevalence rates, cost-benefit analysis, and the intended use of the test.

Regarding Dr. Martin's comment, we know that both the resistance index and the systolic/diastolic ratio are estimated from the same parameters, the peak systolic and end-diastolic frequency shifts, but they have different formulations. Because of its unique formulation, the systolic/diastolic ratio increases in an exponential manner with the progressive decline of the end-diastolic frequency shift, and it reaches the value of infinity with the absent end-diastolic flow. That is why this index not only becomes insensitive beyond a certain point, but also demonstrates maximum total variance of all the indices that we have measured. Thus, although one of these indices can be mathematically derived from the other, their diagnostic efficacies are not identical.

In relation to the outcome parameters, we have investigated the efficacy of the systolic/diastolic ratio in diagnosing intrauterine growth retardation. As we know, it is a multietiologic phenomenon, and, in our experience, the Doppler velocimetry probably does not offer the best method for diagnosing this condition.

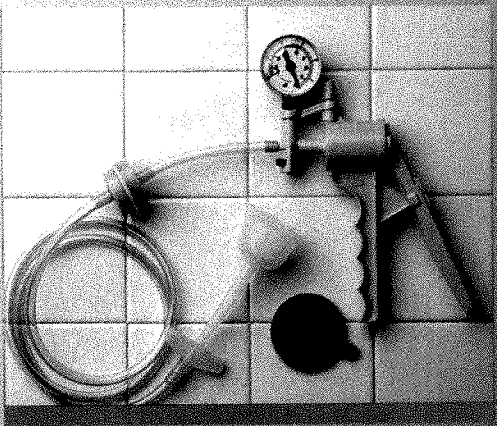
CALL FOR DETAILS

We've Been Giving Doctors A Hand For Over Twenty Years.

And they've given us a hand in designing and refining the best obstetrical vacuum delivery system available.

Over twenty years ago, the Mityvac vacuum delivery system was introduced to provide an alternative method of delivery assistance. In that time we've learned a great deal about our system from the professionals who use it, and have incorporated what we've learned into real product improvements. Today, Mityvac is regarded by many obstetric physicians as the safest, most dependable method of vacuum extraction.

The Mityvac Obstetrical Vacuum Delivery System offers benefits available with no other vacuum extraction system, like sensitive fingertip controls which allow the operator to adjust vacuum pressure to coincide with the natural efforts of the mother. In addition, the soft polyethylene extractor cup is flexible enough for ease of insertion, yet seals easily to the infant's scalp distributing tractive force across a large area. The Mityvac system offers greater control and insures minimal trauma to both infant and mother.



In vacuum extraction systems, Mityvac is the name that more obstetric physicians have come to know and depend on than any other. Mityvac…offering a hand for over twenty years.

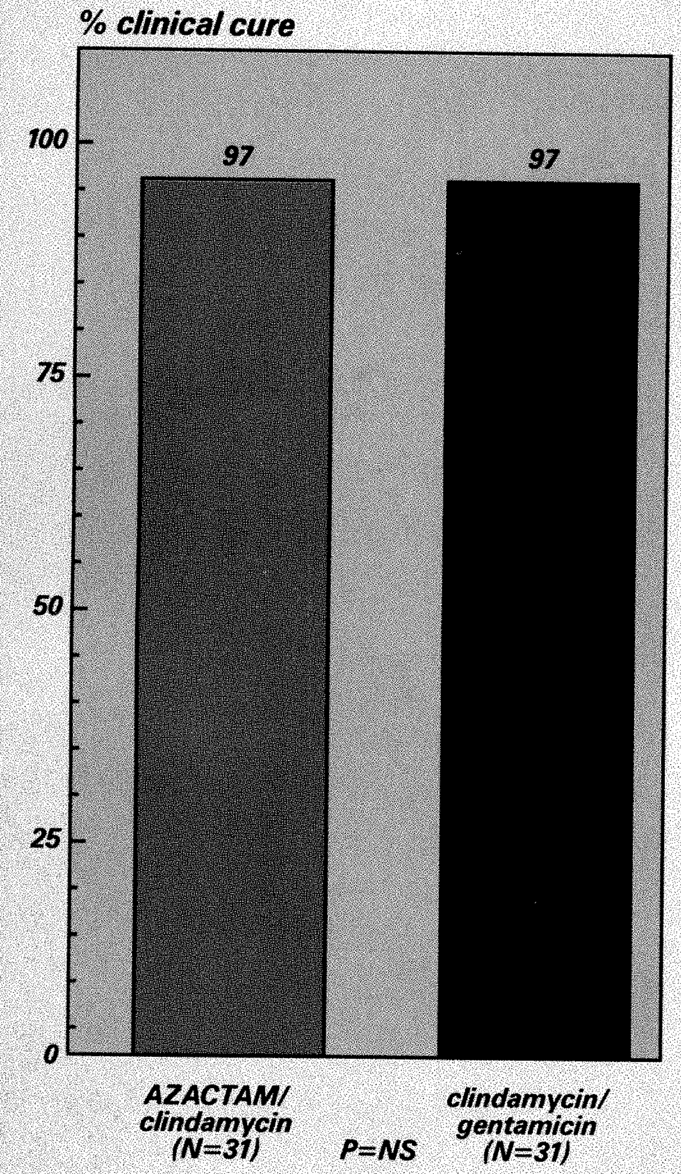
IN POSTPARTUM ENDOMETRITIS*



Azactam®
aztreonam
delivers...

A randomized, comparative trial of AZACTAM versus gentamicin, each with clindamycin, for the treatment of endometritis after delivery.[†]

No universal criteria exist that may satisfy a single definition of "cure." Use of this term may vary between clinical settings and investigators, and the reader is urged to consult the reference listed.

---

[*] Due to susceptible organisms.

[†] Although a useful guide, in vitro data do not necessarily correlate with therapeutic outcome.

[‡] Antibiotics should be given with caution to any patient who has had some form of allergy, particularly to drugs. See full prescribing information for recommendations on patients with immediate hypersensitivity reactions to penicillins.

Following IV administration, the most commonly seen adverse reactions occurred in less than 2% of patients, including local reactions, diarrhea, nausea/vomiting, and rash.

more than you're expecting...

- *Broad aerobic gram-negative in vitro coverage, including Escherichia coli, Proteus mirabilis, and Enterobacter cloacae.*[†]
- *Greater than 90% cure rates in combination with clindamycin.*[1-3]
- *No time-consuming, costly, routine therapeutic drug monitoring.*
- *May be admixed in the same bag with clindamycin.*
- *May be used in penicillin-allergic patients.*[‡]
- *Pregnancy Category B.*

There are no adequate and well-controlled studies in pregnant women. AZACTAM should be used in pregnant women only if clearly needed.

Azactam®
-aztreonam

A logical alternative to aminoglycosides.

Please see adjacent page for brief summary of prescribing information.

Azactam®
aztreonam

AZACTAM* FOR INJECTION
Aztreonam For Injection

DESCRIPTION–AZACTAM (aztreonam, Squibb) is the first member of a new class of antibiotics classified as monobactams. AZACTAM is a totally synthetic bactericidal antibiotic with activity against a wide spectrum of gram-negative aerobic pathogens. The monobactams, having a unique monocyclic beta-lactam nucleus, are structurally different from other beta-lactam antibiotics.

AZACTAM For Injection is a sterile, nonpyrogenic, sodium-free, white to yellowish-white lyophilized cake, containing approximately 780 mg arginine per gram of aztreonam for intramuscular or intravenous use following constitution. Aqueous solutions of the product have a pH in the range of 4.5-7.5.

INDICATIONS AND USAGE–Before initiating treatment with AZACTAM, appropriate specimens should be obtained for isolation of the causative organism(s) and for determination of susceptibility to aztreonam. Treatment with AZACTAM may be started empirically before results of the susceptibility testing are available; subsequently, appropriate antibiotic therapy should be continued.

AZACTAM For Injection is indicated for the treatment of the following infections caused by susceptible gram-negative microorganisms: **Urinary Tract Infections** (complicated and uncomplicated), including pyelonephritis and cystitis (initial and recurrent) caused by *Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa, Enterobacter cloacae, Klebsiella oxytoca*, Citrobacter* species* and *Serratia marcescens**. **Lower Respiratory Tract Infections,** including pneumonia and bronchitis caused by *Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Haemophilus influenzae, Proteus mirabilis, Enterobacter* species and *Serratia marcescens**. **Septicemia** caused by *Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Proteus mirabilis*, Serratia marcescens** and *Enterobacter* species. **Skin and Skin-Structure Infections,** including those associated with postoperative wounds, ulcers and burns caused by *Escherichia coli, Proteus mirabilis, Serratia marcescens, Enterobacter* species, *Pseudomonas aeruginosa, Klebsiella pneumoniae,* and *Citrobacter* species*. **Intra-abdominal Infections,** including peritonitis caused by *Escherichia coli, Klebsiella* species, including *K. pneumoniae, Enterobacter* species including *E. cloacae*, Pseudomonas aeruginosa, Citrobacter* species* including *C. freundii** and *Serratia* species* including *S. marcescens**. **Gynecologic Infections,** including endometritis and pelvic cellulitis caused by *Escherichia coli, Klebsiella pneumoniae*, Enterobacter* species* including *E. cloacae**, and *Proteus mirabilis**.

AZACTAM is indicated for adjunctive therapy to surgery in the management of infections caused by susceptible organisms, including abscesses, infections complicating hollow viscus perforations, cutaneous infections and infections of serous surfaces. AZACTAM is effective against most of the commonly encountered gram-negative aerobic pathogens seen in general surgery.

Concurrent Therapy–Concurrent initial therapy with other antimicrobial agents and AZACTAM is recommended before the causative organisms(s) is known in seriously ill patients who are also at risk of having an infection due to gram-positive aerobic pathogens. If anaerobic organisms are also suspected, therapy should be initiated using an antianaerobic agent concurrently with AZACTAM. Certain antibiotics (e.g., cefoxitin, imipenem) may induce high levels of beta-lactamase *in vitro* in some gram-negative aerobes such as *Enterobacter* and *Pseudomonas* species, resulting in antagonism to many beta-lactam antibiotics including aztreonam. These *in vitro* findings suggest that such beta-lactamase inducing antibiotics not be used concurrently with aztreonam. Following identification and susceptibility testing, appropriate antibiotic therapy should be continued.

CONTRAINDICATIONS–Aztreonam is contraindicated in patients with known allergy to this antibiotic.

WARNINGS–Pseudomembranous colitis has been reported with nearly all antibacterial agents, including aztreonam, and may range in severity from mild to life-threatening. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is one primary cause of "antibiotic-associated colitis."

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to drug discontinuation alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an oral antibacterial drug effective against *C. difficile* (e.g., vancomycin). Careful inquiry should be made for a history of hypersensitivity reaction to any antibiotic or other drugs. Antibiotics should be given with caution to any patient who has had some form of allergy, particularly to drugs. It is recommended that patients who have had immediate hypersensitivity reactions (e.g., anaphylactic or urticarial) to penicillins and/or cephalosporins should be followed with special care. If an allergic reaction to aztreonam occurs, discontinue the drug and institute supportive treatment as appropriate (e.g., maintenance of ventilation, pressor amines, antihistamines, corticosteroids). Serious hypersensitivity reactions may require epinephrine and other emergency measures.

PRECAUTIONS–General: In patients with impaired hepatic or renal function, appropriate monitoring is recommended during therapy. If an aminoglycoside is used concurrently with aztreonam, especially if high dosages of the former are used or if therapy is prolonged, renal function should be monitored because of the potential nephrotoxicity and ototoxicity of aminoglycoside antibiotics. The use of antibiotics may promote the overgrowth of nonsusceptible organisms, including gram-positive organisms and fungi. Should superinfection occur during therapy, appropriate measures should be taken.

Carcinogenesis, Mutagenesis, Impairment of Fertility–Carcinogenicity studies in animals have not been performed. Genetic toxicology studies performed *in vivo* and *in vitro* with aztreonam in several standard laboratory models revealed no evidence of mutagenic potential at the chromosomal or gene level. Two-generation reproduction studies in rats at daily doses up to 20 times the maximum recommended human dose, prior to and during gestation and lactation, revealed no evidence of impaired fertility. There was a slightly reduced survival rate during the lactation period in the offspring of rats that received the highest dosage, but not in offspring of rats that received five times the maximum recommended human dose.

Pregnancy–Pregnancy Category B: Aztreonam crosses the placenta and enters the fetal circulation. Studies in pregnant rats and rabbits, with daily doses up to 15 and 5 times, respectively, the maximum recommended human dose, revealed no evidence of embryo- or fetotoxicity or teratogenicity. No drug induced changes were seen in any of the maternal, fetal or neonatal parameters that were monitored in rats receiving 15 times the maximum recommended human dose of aztreonam during late gestation and lactation. There are no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, aztreonam should be used during pregnancy only if clearly needed.

Nursing Mothers–Aztreonam is excreted in breast milk in concentrations that are less than 1% of concentrations determined in simultaneously obtained maternal serum; consideration should be given to temporary discontinuation of nursing and use of formula feedings.

Pediatric Use–Safety and effectiveness have not been established in infants and children.

ADVERSE REACTIONS–Local reactions such as phlebitis/thrombophlebitis following IV administration, and discomfort/swelling at the injection site following IM administration occurred at rates of approximately 1.9% and 2.4%, respectively. Systemic reactions (considered to be related to therapy or of uncertain etiology) occurring at an incidence of 1 to 1.3% include diarrhea, nausea and/or vomiting, and rash. Reactions occurring at an incidence of less than 1% are listed within each body system in order of decreasing severity; *Hypersensitivity*–anaphylaxis. *Hematologic*–pancytopenia, neutropenia, thrombocytopenia, anemia, leukocytosis, thrombocytosis. *Gastrointestinal*–abdominal cramps; rare cases of *C. difficile*-associated diarrhea, including pseudomembranous colitis, or gastrointestinal bleeding have been reported. Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment (see WARNINGS). *Dermatologic*–purpura, erythema multiforme, urticaria, exfoliative dermatitis, petechiae, pruritus, diaphoresis. *Cardiovascular*–hypotension, transient ECG changes (ventricular bigeminy and PVC). *Respiratory*–one patient experienced flushing, chest pain, and dyspnea. *Hepatobiliary*–hepatitis, jaundice. *Nervous System*–seizure, confusion, vertigo, paresthesia, insomnia, dizziness. *Musculoskeletal*–muscular aches. *Special Senses*–tinnitus, diplopia, mouth ulcer, altered taste, numb tongue, sneezing and nasal congestion, halitosis. *Other*–vaginal candidiasis, vaginitis, breast tenderness. *Body as a Whole*–weakness, headache, fever, malaise.

Adverse Laboratory Changes–Those reported without regard to drug relationship during clinical trials were: *Hepatic*–elevations of AST (SGOT), ALT (SGPT), and alkaline phosphatase; signs or symptoms of hepatobiliary dysfunction occurred in less than 1% of recipients (see above). *Hemic*–increases in prothrombin and partial thromboplastin times, eosinophilia, positive Coombs test. *Renal*–increases in serum creatinine.

OVERDOSAGE–If necessary, aztreonam may be cleared from the serum by hemodialysis and/or peritoneal dialysis.

DOSAGE AND ADMINISTRATION–Dosage adjustments are recommended for patients with impaired renal function. In elderly patients, estimates of creatinine clearance should be obtained and appropriate dosage modifications made if necessary.

HOW SUPPLIED–AZACTAM For Injection (Aztreonam For Injection)–Lyophilized–is supplied in single-dose 15 mL vials containing **500 mg,** or **1 g**/vial; in single-dose 30 mL vials containing **2 g**/vial; and in single-dose 100 mL intravenous infusion bottles containing **500 mg** or **1 g** or **2 g**/bottle.

Consult package insert before prescribing AZACTAM (aztreonam). (J4-231C)

Vaginal birth after cesarean section: The impact of patient resistance to a trial of labor

Gerald F. Joseph, Jr., MD, Charles M. Stedman, MD, and Alfred G. Robichaux, MD
New Orleans, Louisiana

In spite of the relative safety and medical advantages of vaginal birth after cesarean section, the procedure continues to be underutilized in the private practice setting. To evaluate the hypothesis that resistance by the patient often precludes a trial of labor, an observational study was conducted of all women with a history of one prior cesarean section who were delivered in 1989 at Ochsner Foundation Hospital. The choices of 167 women and the judgments of their obstetricians were longitudinally recorded during the antepartum and intrapartum course. Patients routinely received the patient guide of the American College of Obstetricians and Gynecologists for vaginal birth after cesarean section. Ultimately, 50% of patients who were encouraged by their obstetrician toward vaginal birth after cesarean section opted for an elective repeat cesarean section without a trial of labor. Reasons for patient resistance are enumerated and potential future remedial proposals are discussed. (AM J OBSTET GYNECOL 1991;164: 1441-7.)

Key words: Vaginal birth after cesarean, repeat cesarean section, decision making

Vaginal birth after cesarean section (VBAC) rose to the forefront of obstetric controversy in the 1980s. Review of the literature suggests that the long-taught principle of "once a section, always a section" is no longer the best approach.[1,2] On Oct. 26, 1988, the American College of Obstetricians and Gynecologists (ACOG) updated their guidelines concerning vaginal delivery after previous cesarean section. The ACOG Committee on Obstetrics: Maternal and Fetal Medicine stated: "The concept of routine repeat cesarean birth should be replaced by a specific indication for a subsequent abdominal delivery and in the absence of a contraindication, a woman with one previous cesarean delivery with a low transverse incision should be counseled and encouraged to attempt labor in her current pregnancy."[3] This latest ACOG guideline endorses a concept of management that obligates the obstetrician to include the patient in planning the approach to delivery.

For 4 years the Department of Obstetrics and Gynecology at the Ochsner Clinic has had an active VBAC program. Ours are private patients and as such have retained an active role in matters pertaining to their health care. Even though we have encouraged all eligible patients to consider VBAC, some have refused. It is our perception that it is often the reluctance of the patient, not her obstetrician, that prevents greater utilization of VBAC. An interest in verifying or refuting this perception provided the incentive for this study.

Material and methods

The study population consisted of all patients with a history of one previous cesarean section who were delivered at the Ochsner Foundation Hospital between Jan. 1 and Dec. 31, 1989. All patients were managed throughout pregnancy by one of seven obstetricians at the Ochsner Clinic in New Orleans.

Patients were included in this study if they met the following criteria: (1) one previous low-transverse cesarean section, (2) singleton fetus, (3) cephalic fetal presentation, and (4) candidate for epidural anesthesia. Patients were excluded from the study for the following reasons: (1) medical complications of pregnancy necessitating immediate delivery or (2) ominous antepartum fetal heart rate testing that contraindicated a trial of labor.

Each patient was given a copy of the ACOG patient education pamphlet entitled "Vaginal Birth After Cesarean Delivery."[4] A report of the previous delivery was obtained, and specifics of the previous labor and the type of uterine scar were ascertained. On the basis of the obstetric history and pelvic examination early in pregnancy, the obstetrician recorded his/her initial preference as to mode of delivery. Each patient's initial choice as to delivery preference was likewise recorded after verbal discussion and review of the ACOG pamphlet. Changes in the patient's decision or the obstetrician's opinion were tracked longitudinally during the pregnancy along with specific explanations.

From the Department of Obstetrics and Gynecology, Ochsner Clinic and Alton Ochsner Medical Foundation.

Presented at the Fifty-eighth Annual Meeting of the Central Association of Obstetricians and Gynecologists, Louisville, Kentucky, October 11-13, 1990.

6/6/28939

Table I. Patients excluded from study

Reason for exclusion	*No. of patients (n = 24)*
Vertical uterine incision	7
Abnormal presentation at term	8
Maternal medical complications	3
Abnormal antepartum testing	2
Multiple gestation	3
Lumbar disc disease precluding epidural anesthesia	1

Table II. Reasons for refusal of VBAC in group IV

Cited reason	*No. of patients (n = 41)*
Fear of labor	24
Convenience of scheduled delivery	11
Fear of recurrent outcome	6

Patients were considered "poor" VBAC candidates if, in the judgment of the obstetrician, they had a clinically contracted pelvis. All others were considered "good" VBAC candidates.

Oxytocin augmentation was freely utilized for the usual obstetric indications. Induction of labor was not offered routinely. Patients understood that epidural anesthesia was available on a 24-hour basis.

Results

A total of 167 patients with one previous cesarean section received their prenatal care and were delivered at the Ochsner Medical Institutions during the study period. This group represented 13% of the 1254 deliveries in 1989. Of these 167 patients, 24 (14.4%) were excluded from the study (Table I). For the purposes of this study 143 (85.6%) patients were considered VBAC candidates.

Of the 143 potential candidates, 12 (8.3%) were advised by their obstetricians early in the pregnancy that they were "poor" VBAC candidates (group I). None of these patients was encouraged by her obstetrician to attempt VBAC but by ACOG guidelines a trial of labor was not precluded. All of these patients elected a repeat cesarean section without a trial of labor. The weight of the newborns at the time of repeat cesarean section was greater than the weight at the time of the initial cesarean section in 9 of these 12 cases. The mean weight of the newborns at repeat section was 3500 gm as compared with 3256 gm at the primary cesarean section.

Group II consisted of patients judged to be "good" candidates for VBAC by their obstetricians and who consistently chose to attempt a vaginal delivery. Of the 143 patients, 46 (32.2%) were in this group and 30 of 46 (65.2%) achieved a vaginal delivery. Cephalopelvic disproportion was cited as the indication for a repeat cesarean section in 14 of the 16 patients who were unable to have a vaginal delivery. Patients 15 and 16 underwent repeat cesarean section because of fetal distress. The mean birth weight in the group delivered vaginally was 3210 gm (range 1240 to 4508 gm) whereas the mean weight in the group with unsuccessful trial of labor was 3543 gm (range 2700 to 4111 gm).

Group III consisted of 5 (3.5%) "good" candidates for VBAC who initially chose not to have a trial of labor. Three of these patients cited "fear of recurrent outcome" and two "convenience" as reasons for initially opting for repeat cesarean section. These patients subsequently abandoned their choice of elective repeat cesarean section when admitted in active labor between 12 and 24 days before the estimated date of confinement. All five were delivered vaginally.

Group IV consisted of 41 of 143 (28.7%) who were considered "good" candidates but who steadfastly refused a trial of labor. The primary reasons given by these patients for electing a repeat cesarean section without a trial of labor are seen in Table II.

Group V consisted of 39 of 143 (27.3%) "good" candidates who initially planned to attempt VBAC but who ultimately were delivered by repeat cesarean section without a trial of labor. Eleven patients (subgroup Va) initially chose VBAC in early pregnancy but later changed their minds despite continued encouragement by their obstetricians to pursue VBAC. All 11 cited "convenience" as their primary reason for change in plans.

Twenty-eight patients (subgroup Vb) initially chose VBAC in early pregnancy and were initially judged to be "good" candidates for a trial of labor but were advised by their obstetricians at term that there was a diminishing chance of vaginal delivery. Twenty-seven of 28 were considered to have an estimated fetal weight exceeding pelvic capacity. Ninety-three percent of these patients had had a primary cesarean section because of cephalopelvic disproportion. The mean birth weight at repeat cesarean section was 3886 gm.

The evolution of choices in "resistant" and "receptive" patients is illustrated in Figs. 1 and 2.

Comment

The medical literature in the past decade is replete with the low maternal and perinatal morbidity and mortality associated with VBAC.[5-11] Positional statements at the national level began in 1980 when the National Institutes of Health Consensus Conference on Cesarean Section convened in response to the sharply rising rate in cesarean births. On the basis of the available literature, this body suggested VBAC as one potential solution to the rising cesarean rate.[12] In 1982 ACOG issued their first guidelines relative to VBAC and deemed the procedure an acceptable option.[13] In 1985 VBAC guidelines were further expanded by ACOG.[14] The most recent guidelines, which were released in October 1988, cited VBAC as the preferred mode of delivery.[3]

Despite these reassuring data, VBAC has been slow to develop as a reality for many obstetricians. A hospital-based study in 1988 found only 12.6 VBAC deliveries per 100 women with previous cesarean sections.[15] Is this perpetuated utilization of repeat cesarean section in seven of eight cases a physician-driven or patient-driven phenomenon? Physician factors suggested as possible deterrents to a trial of labor have included failure to gain experience with VBAC during training years, the convenience of a scheduled delivery, fear of litigation, and even the issue of higher fees for abdominal delivery.

Surprisingly, there is a paucity of information regarding the attitudes and opinions of patients reluctant to agree to a trial of labor.[16, 17] Kirk et al.[16] sought to document reasons that patients chose repeat cesarean section by use of a retrospective questionnaire sent to postpartum patients. Six reasons were listed for choosing repeat cesarean section. The two major factors cited were avoidance of pain of labor and perceived low probability of vaginal delivery. Seventy-three percent of patients choosing repeat cesarean section reported their obstetricians either discouraged VBAC or had a neutral or unknown attitude. Unfortunately, statistical analysis was impaired by the 62% return rate. In our study we sought to eliminate many of the variables that might dissuade patients from a trial of labor.

The first national survey of ACOG members regarding attitudes and practices concerning VBAC was conducted in March 1990 and reported in late August 1990.[18] This survey found that approximately 60% of patients given the option chose VBAC. The survey may suffer from recall bias on the part of the responders, and therefore any conclusion drawn from these numbers must be suspect.

In our study group, 59% (groups II and V) *initially* chose to attempt a trial of labor (Fig. 1). However, *ultimately*, 64.3% (groups I, IV, and V) opted for an elective repeat cesarean section without a trial of labor (Fig. 2). Of the 85 patients who initially chose VBAC, 39 (group V) became disenchanted with the prospect of VBAC late in the pregnancy and opted for elective repeat cesarean section. By this time in the pregnancy, 28 (subgroup Vb) of these 39 patients were negatively influenced by their obstetricians' predictions of diminishing success if a course of VBAC was pursued. However, 11 (group Va) of the 39 opted for an elective repeat cesarean section despite continued enthusiasm and encouragement toward VBAC by their obstetricians. These 11 patients (subgroup Va) plus the 41 patients (group IV) who steadfastly opted for elective repeat cesarean section throughout pregnancy represent the total number of "resistant" patients in our study. In summary, 72% of candidates (groups II, III, and IV and subgroup Va) were given continued encouragement to pursue VBAC, yet only half of these opted for a trial of labor.

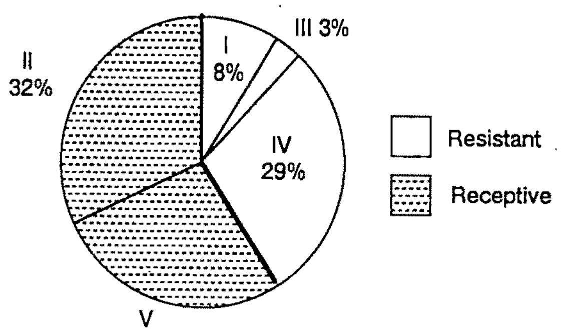

Fig. 1. Pie graph showing initial choice regarding trial of labor of each patient ($N = 143$) according to groups.

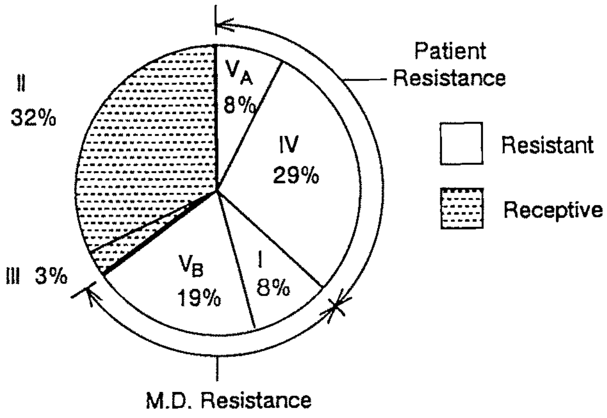

Fig. 2. Pie graph showing final choice regarding trial of labor of each patient ($N = 143$) according to groups. Patient-directed resistance and physician-directed resistance are shown.

Of the 51 patients with attempted VBAC (groups II and III), success was reported in 35 (68.6%), which is near the success rate quoted in other studies.[10, 19-21] In only five cases (group III) was the obstetrician able to change the patient's mind in favor of VBAC; in all of these cases the patient presented in active labor significantly before the estimated date of confinement.

Quantitating the influence of the obstetricians on the decisions made by their patients is most difficult. "Enthusiasm" for VBAC surely must vary depending on many interactions between the patient and her obstetrician.[16] By giving each patient an informational pamphlet, we provided an unbiased view of the subject for the patients' careful consideration. Certainly, the "negative" influence exerted by the obstetrician with regard to the 12 patients in group I and the 28 patients in subgroup Vb had a profound influence on their decision-making process. These 40 of 143 patients (28%) represent the "resistance" to VBAC by the obstetricians in our study. Undoubtedly, had all of the 40 patients been subjected to a trial of labor, some of these patients may have been delivered vaginally.[22-24] We remain convinced, however, that most of these patients would have labored unsuccessfully and feel supported in this belief by the birth weights.

Our study reveals that reluctance toward VBAC does not emanate exclusively from the obstetrician but also comes from some patients and that, despite efforts to provide a supportive setting, many patients still prefer operative delivery by repeat cesarean section rather than a trial of labor. These patients apparently view repeat cesarean delivery as an advantageous procedure that allows a known time of delivery without the uncertainties of attempted VBAC. Medical concerns pertaining to costs and safety seem to be overlooked by such patients.

Fear and inconvenience appear to be by far the most commonly cited deterrents to VBAC. One possibility is that some patients had already decided on repeat cesarean section even before conception. It may be that educational literature and physician counseling should be offered immediately after the primary cesarean section rather than held until a subsequent pregnancy as suggested by Kirk et al.[16] In our opinion enhanced patient education and neutralization of the convenience factor should theoretically reduce patient resistance to a trial of labor in the future. Perhaps this type of approach would be preferable to a protocol of mandated trial of labor.

Discussion

Dr. Fredrik F. Broekhuizen, Milwaukee, Wisconsin. A recent report by the National Center for Health Statistics analyzing international differences in obstetric interventions indicated that in 1985 the United States had a 6.6% rate of women with a previous cesarean section who were delivered vaginally versus 3.4% in 1980.[1] It is likely that by now this percentage has further increased with continuing acceptance of VBAC and application of the ACOG guidelines regarding VBAC. I doubt that the national percentage, reaching 12.6% in a hospital-based study[2] in 1988, reached the 20.9% rate reported in this series in 1989. In several European countries, no significant changes in VBAC rates were seen between 1980 and 1985 with rates in 1985 ranging from 39.3% in Scotland to 55.4% in The Netherlands. Rates in these ranges might represent rather high targets, which are achievable at a national level, since they are reached in countries with medical practice climates where the management plans after a previous cesarean section are predominantly determined, if not mandated, by an obstetrician, and the patient is not likely to play as active a role in the decision-making process. Since the "once a section . . ." principle was never accepted in these countries mentioned, we can assume that the choice for a repeat cesarean section is not based on adherence to an outdated practice or resistance to a change in practice by obstetrician or patient. On the other hand, with lower primary cesarean section rates, a higher percentage of recurrent indications for repeat cesarean section would negatively influence the VBAC rates.

A 20.9% rate, given this background, after a 4-year VBAC program in a private-practice setting and with a nonmandated approach, is in my opinion not as disappointing as the authors indicate. It will require many more years before we will observe a final effect of the ACOG guidelines, which opened the door only in 1985 for a universally acceptable VBAC practice. In the largest reported VBAC series in the United States, 38% of patients with a previous cesarean section underwent a trial of labor with a 75% success rate and a vaginal delivery rate of 28.5% for all patients with a previous cesarean section (unpublished observations).

How unbiased or biased is counseling for a trial of labor? Is the ultimate summarizing message heard by the patient: "VBAC is safe, a recommended and optimal management for you, but you have the right to refuse this medically sound advice and elect a repeat cesarean?" Or is the message heard: "VBAC is safe, a reasonable and medically sound option, but truly, it's totally your choice?" I submit to you that we all have observed or even utilized both approaches, perceiving both as carrying the spirit of the ACOG guidelines, and that we assume that different VBAC rates will result. I feel the authors missed an opportunity to assess the patient's perception of the actual counseling message as an interfering factor for acceptance or rejection. Kirk et al.[3] concluded, as did the authors, that social exigencies appeared to play a more important role than assessment of medical risks in patient decisions. It is reported that physicians in public hospitals exert more influence on patient's decisions[3]—a subtle shift to mandate? In my own institution, with a distinct "we recommend, but" type of educational message, between 1985 and 1989 we saw the repeat cesarean section rate decrease from 9.5% to 5.0% and the VBAC rate rise from 2.1% to 5.5% of all deliveries. Of all patients with a previous cesarean section, 40.9% were delivered vaginally.

Would the authors address the following questions. First, how would they characterize the message sent by their group to their patients? Second, does their group's approach to VBAC deviate significantly from the approach taken by other obstetricians in their community and to what extent could that have influenced their patients' attitudes?

DR. JAMES R. SCOTT, Salt Lake City, Utah. Because repeat cesarean section has contributed to the rising cesarean section rate, obstetricians and their patients have been strongly encouraged to attempt a trial of labor with subsequent pregnancies. The purpose of this study was specifically to investigate the incidence and reasons for patient refusal of VBAC. This is certainly a topic of current interest to all obstetricians since physicians often have been blamed for the slow acceptance of this concept. The prospective study design was satisfactory, but more information about the patients' ages, education, and socioeconomic status is needed to determine whether the results could be interpolated to other populations. It would also be helpful to provide more details on exactly *why* the patients refused a trial of labor. For example, were the women with a fear of labor or recurrent outcome those who had long, painful labors, poor outcomes, or complications associated with their labors that resulted in the previous cesarean section? In my experience these often have been factors. Moreover, an interesting group of patients that have received little attention in most publications on VBAC are those who again have failure of the trial of labor. These considerations are illustrated by two of my own patients who were delivered within 2 weeks of each other:

The first patient was delivered of a 4000 gm infant by cesarean section at 42 weeks' gestation in her first pregnancy after a long and difficult first stage of labor with a transverse arrest in the second stage. She did not want to go through that again, and I thought she again had a macrosomic infant. She underwent an uncomplicated repeat cesarean section, again was delivered of a 4000 gm infant at 39 weeks, was discharged in 3 days, and had a total hospital bill of $2,408.

The second patient's first cesarean section was because of a breech presentation, and she wanted a postpartum tubal sterilization. She also was not enthusiastic about VBAC, but I convinced her to try it. This time she had a long labor with many vaginal examinations. She pushed for >2 hours in the second stage, but the presenting vertex remained high. She was again eventually delivered by cesarean section, and a tubal ligation was done. The baby did well, but the patient was febrile and required antibiotics. A wound infection developed and she was in the hospital 9 days with a total cost of hospitalization of $5,806.

In other words, the patient that I persuaded to attempt a trial of labor failed after about 24 hours of labor, was in the hospital three times as long, and had a hospital bill more than twice as high as that of the patient who had a repeat cesarean section. Which patient do you think was happiest with her management?

Do the authors have any information on the patient satisfaction and complication rates of those patients who failed a trial of labor as compared with those who simply underwent repeat cesarean section or had a successful VBAC?

Although VBAC appears to be a safe and desirable option, it should be pointed out that none of the studies reported in the literature have been prospective trials randomizing repeat cesarean section with a trial of labor to actually prove that maternal and neonatal outcomes are better with the latter. In our own metropolitan area, since 1982 there have been 12 known uterine ruptures with attempted VBAC, which have resulted in three perinatal deaths and two severely damaged infants; in four of these cases litigation has occurred or is in progress.

Finally, I believe that the most interesting question this study raises is just how strongly the physician should encourage, persuade, or even coerce a patient to attempt a trial of labor if she prefers a repeat cesarean section. In my mind this question has never been satisfactorily addressed either medically or legally. Originally, the National Institutes of Health consensus group recommended offering VBAC to selected patients; ACOG guidelines later stated that VBAC should be encouraged for all patients, and others have implied that the patient should be given no choice. This has apparently now led some third-party payers to require a trial of labor.

Therefore what did the authors learn from their study that will be helpful to all of us confronted with the present situation? Do they recommend that we continue to encourage patients to participate in the decision regarding the route of delivery even if some refuse VBAC? On the other hand, if they believe that patient acceptance of VBAC should be increased, exactly what "enhanced patient education" and "neutralization of the convenience factor" do they recommend, and what is the evidence that these measures will be effective?

I congratulate the authors on their timely study.

Dr. Washington Hill, Nashville, Tennessee. The authors do show that resistance for VBAC does not emanate completely from the obstetrician. They also show that the obstetricians play a very important part.

I would like to draw attention to two groups of the authors—group I and group Vb. What is meant by "clinically abnormal pelvis" and what is meant by "larger than pelvic capacity at term"? Those two terms are one of the reasons why physician resistance occurs.

Dr. Leland R. Matthews, Bloomington, Indiana. I applaud your study of this important clinical problem. I think in our practice the resistance of the patient with prior cesarean section to again experience labor is the single greatest obstacle to VBAC. However, I have a question. Why does a VBAC candidate also have to be a candidate for epidural anesthesia?

Dr. Peter F. Fehr, St. Paul, Minnesota. I was going to ask the same question. In the review of our VBAC rate, we've discovered that our resident clinic, which has an expectation of VBAC, has the best VBAC rate in our institution whereas some of our obstetricians have a zero VBAC rate. In fact, some of the patients are moving to other obstetricians who are willing to do VBACs.

My question is was there a difference between physicians? The other question I ask is what is the approach at the time of the primary cesarean section? We discovered that many of the patients that come into our program have been told essentially nothing or basically have been told that they should not consider a VBAC at the time of their first cesarean section.

Those who have originally said, well, you can probably plan a vaginal delivery the next time, come into their next pregnancy with a totally different attitude. I think the way you end up with your first cesarean section is to scare the patient. You actually prepare her for a VBAC or a non-VBAC for the next delivery.

Secretary-Treasurer Anderson. Was there any impact of third-party payers demanding VBAC consideration? Did this influence your study?

Dr. Joseph (Closing). I thank Dr. Broekhuizen and Dr. Scott for their discussion and I also appreciate the other interest. I think that VBAC and repeat cesarean section is a difficult topic. It's a topic that interested us enough to spend 1 year tracking our results. Basically we did so because we just wanted to see what we were doing.

Dr. Scott asked what we learned from the study. I think we learned that perhaps the best way to handle VBAC is to continue to be good clinicians.

One of the floor questions was what we considered a small pelvis. Basically this was not an x-ray diagnosis but a clinical diagnosis made by the experienced obstetrician. The "big" fetus was "big" mostly by ultrasonography, but it was a *relative* "big." The fetus didn't necessarily have to weigh 4200 or 4000 or 3800 gm. It was relatively big for the mother's pelvis; again, these were clinical decisions.

Dr. Broekhuizen asked what did we think our counseling message was. Everybody's counseling message is a little different. Our counseling message was "We recommend," much like his. I think if patients are given the ACOG pamphlet and physicians talk to them about their chances of vaginal delivery and about their complications, patients elect different things. Some patients may elect a primary cesarean section because of the fear of herpes, even if they've had herpes once in their life, and sometimes you can't talk them out of that.

Dr. Matthews asked about epidural anesthesia. What we tried to do was to put in this group only those patients who could not lay blame on not wanting a VBAC on anything else. They knew they had the availability of anesthesia, so they couldn't say, "I don't want to do VBAC because you don't have anesthesia." It's not that all patients had epidural anesthesia, although most of our patients do.

I doubt very seriously that our VBAC rate is totally different from others in the community. We do have a teaching program at our hospital, so maybe we are a little more liberal in our policies for VBAC than other institutions, but by no means would I consider our institution to be known for its VBAC program.

Dr. Anderson asked about third-party payers. Third-party payers were tracked in this study but not reported here. A large number of our patients are health maintenance organization patients; interestingly enough, their outcome was no different than the outcome for private patients.

Again, in conclusion, I would say that one of the things we learned from this study is that perhaps the time of the primary cesarean section is the time that counseling for the next delivery should start. Patients are often discouraged at this time, and they look down the road to see more cesarean sections, and it's certainly at that time that the ground should be laid for the method of delivery in future pregnancies.

Pregnancy rates after peritoneal ovum-sperm transfer

Carolyn B. Coulam, MD, Albert J. Peters, DO, Mark Gentry, MD, William Gentry, MD, Elizabeth S. Critser, PhD, and John K. Critser, PhD
Indianapolis, Indiana

We present the technique of peritoneal ovum-sperm transfer as an option for treatment in couples with unexplained infertility factors. In 1989 we reported the first successful pregnancy, in the United States, after transferring sperm and oocyte into the peritoneal cavity. We now report the results of a prospective study of this procedure. Twelve women with unexplained infertility underwent 23 cycles of peritoneal ovum-sperm transfer. Ovulation stimulation was achieved with human menopausal gonadotropin. Ultrasonographically directed oocyte recovery was performed by the transvaginal route with the patient under local anesthesia and sedation. After oocyte recovery, 4.5 ± 0.4 (mean ± SE) oocytes and 13.3 ± 1.0 (mean ± SE) × 10^6 motile spermatozoa were transferred into the pouch of Douglas. Six clinical pregnancies occurred in 23 stimulated cycles for a pregnancy rate of 26% per cycle. This value compares with the overall pregnancy rates of 16% for in vitro fertilization and 27% for gamete intrafallopian transfer reported by the In Vitro Fertilization Registry. Thus these preliminary data suggest that peritoneal ovum-sperm transfer is at least as successful as in vitro fertilization and gamete intrafallopian transfer. Advantages of peritoneal ovum-sperm transfer over gamete intrafallopian transfer include its being an office nonsurgical procedure not necessitating a general anesthetic and decreased cost. Therefore peritoneal ovum-sperm transfer is a reasonable first approach in couples with unexplained infertility. (Am J Obstet Gynecol 1991;164:1447-52.)

Key words: Peritoneal ovum-sperm transfer

Infertility is a significant public health concern affecting an estimated 3 million couples in the United States.[1] Despite complete investigation, the cause of infertility is unexplained in approximately 20% of couples.[2] For treatment of these individuals, assisted reproductive techniques have become increasingly more common over the last decade. The procedure associated with the highest pregnancy rate reported to the In Vitro Fertilization Registry[3] is gamete intrafallopian transfer. Pregnancy rates after this procedure are reported to be 27% per cycle in which gametes were transferred.[3] However, to achieve these results an operative procedure and a general anesthetic are required. Pregnancies after transfer of oocytes and sperm into the peritoneal cavity with local anesthesia and sedation in an

office setting have been documented.[4-6] We have previously reported the first pregnancy resulting from peritoneal ovum-sperm transfer in the United States[4] and the lack of production of sperm antibodies in women undergoing intraperitoneal insemination of sperm.[6] We now report results of a prospective study of this procedure by the transvaginal route under ultrasonographic guidance and local anesthesia. Six clinical pregnancies occurred in 12 women undergoing 23 stimulated cycles for a pregnancy rate of 26% per cycle. It is concluded that peritoneal ovum-sperm transfer is as efficacious as gamete intrafallopian transfer in producing pregnancies in couples with unexplained infertility and that it is associated with lower risk and less cost than gamete intrafallopian transfer. Therefore peritoneal ovum-sperm transfer should be considered among the options as a first approach in treatment of couples experiencing unexplained infertility.

Material and methods

Patient population. Twelve couples with the diagnosis of unexplained infertility served as the study population. All of the women had the following normal or negative test results: ovulation documented by urinary luteinizing hormone testing and ultrasonographic monitoring of folliculogenesis[7]; luteal phase serum concentrations of progesterone; in-phase endometrial biopsy specimen; serum levels of thyroid-stimulating hormone, thyroxine, and prolactin; hysterosalpingogram; laparoscopic documentation of bilateral tubal patency, absence of pelvic adhesions, and absence of endometriosis; and negative sperm antibody assays. All of the men had normal semen analyses, normal penetration rates within the hamster egg penetration assay, and negative sperm antibodies. The average age of the women was 30 (range, 26 to 39) years and the mean duration of infertility was 3.9 (range, 2 to 6) years.

Ovarian stimulation and oocyte retrieval. Ovarian stimulation was achieved with intramuscular administration of human menopausal gonadotropin (150 IU/day) beginning on day 3 of the menstrual cycle. The serum estradiol level was monitored daily, typically between days 7 and 12. Luteinizing hormone was measured from urine collected every 8 hours on days 7 through 12. The endocrine parameters, in combination with ultrasonographic data, were used to determine the timing of exogenous administration of human chorionic gonadotropin (hCG) (10,000 IU) and subsequent oocyte retrieval, which occurred 36 hours after human chorionic gonadotropin administration. Follicular aspiration was accomplished by transvaginal, ultrasonographically guided needle aspiration, as previously reported.[5] Follicular contents were collected in Ham's F-10 medium (Gibco, Grand Island, N.Y.) supplemented with 10 mmol/L HEPES and 100 IU/ml heparin. Recovered oocytes were transferred into Ham's F-10 medium supplemented with 15% heat-inactivated fetal cord serum until retransferred to the cul-de-sac.

Sperm preparation. Sperm preparation was performed as previously described.[8] Briefly, the sample was allowed to liquify at room temperature for 30 minutes and then washed twice in Ham's F-10 medium containing 7.5% heat-inactivated fetal cord serum. The sperm pellet was overlaid with 1 ml of Ham's F-10 medium and incubated for 90 minutes at 37° C in a 5% carbon dioxide high-humidity incubator. The supernatant was removed and evaluated for sperm concentration and percent motility.

Gamete transfer procedure. Mature oocytes with approximately 13.3 ± 1.0 (mean ± SE) million motile sperm were transferred in Ham's F-10 medium supplemented with 15% heat-inactivated fetal cord serum into the cul-de-sac under ultrasonographic guidance by a 17-gauge spinal needle and a 3 Fr. Teflon catheter.

Luteal phase support and monitoring. Each woman received vaginal progesterone suppositories (25 mg/day), beginning 48 hours after the procedure for 14 days or until the onset of menses or as long as serum hCG levels were ≥20 mIU/ml. Blood was drawn for hCG determination beginning 10 days after peritoneal ovum-sperm transfer and repeated every 48 hours until onset of menses or demonstration of an intrauterine gestational sac with a 7.5 mHz vaginal ultrasonographic transducer. If hCG was ≥10 mIU/ml, transvaginal ultrasonographic examinations were performed beginning 14 days after peritoneal ovum-sperm transfer and were continued at weekly intervals until fetal heart activity was demonstrated.

Results

Table I summarizes the clinical characteristics of the peritoneal ovum-sperm transfer cycle. Table II describes the gamete characteristics of 23 peritoneal ovum-sperm transfer cycles. After oocyte recovery, 4.5 ± 0.4 oocytes and $13.3 \pm 1.0 \times 10^6$ motile spermatozoa were transferred into the pouch of Douglas. Six clinical pregnancies (26% per cycle) occurred. Three pregnancies terminated in spontaneous abortion before 8 weeks' gestation. One of these embryos had a chromosome analysis revealing 47,XX + 22 and another had 47,XX + 15. Three pregnancies produced six healthy infants (one singleton, one twin, and one triplet gestation). The singleton and twin gestations were delivered at term without complications. The triplets were born at 32 weeks' gestation and weighed between 1107 and 1532 gm. All infants had normal examinations at 1 year of age.

Comment

Assisted reproductive technologies continue to be increasingly important treatments for infertility. They are particularly helpful in treating individuals who suffer from infertility as a result of altered or prevented sperm-egg interaction. Since identification of such subpopulations is limited by available diagnostic tools, most of these couples are first seen for unexplained infertility.

We have previously reported a pregnancy resulting from a transvaginal, ultrasonographically guided peritoneal ovum and sperm transfer.[5] The results of this prospective study suggest that this procedure produces pregnancy in 26% of transfer cycles in couples with unexplained infertility. Pregnancies also have been reported after transabdominal, ultrasonographically guided peritoneal transfer of sperm and oocytes[4] at a rate of 44% per transfer cycle. Pregnancy rates resulting from peritoneal ovum-sperm transfer procedures are summarized in Table III. Overall, 31% of cycles in which gametes are transferred result in clinical pregnancies. No ectopic pregnancies have been reported. The pregnancy rate of 31% per cycle transferred by peritoneal ovum-sperm transfer compares favorably with the pregnancy rate of 27% per cycle transferred reported by the In Vitro Fertilization Registry for gamete intrafallopian transfer.[3] The success rates have led to wide acceptance of gamete intrafallopian transfer. While these initial data suggest that peritoneal ovum-sperm transfer has the same success rate, it has a number of advantages over gamete intrafallopian transfer. Gamete intrafallopian transfer requires a laparoscopy or minilaparotomy, and it is costly and potentially hazardous. Peritoneal ovum-sperm transfer is performed in the office with the patient under local anesthesia and intravenous sedation. The procedure is short in duration (<1 hour) and does not require hospitalization, general anesthesia, or an operative procedure. The cost is considerably less than for gamete intrafallopian transfer (about half). Therefore peritoneal ovum-sperm transfer offers a simpler and safer method for those couples undergoing assisted reproductive techniques for the treatment of unexplained infertility.

Modified from Devroey et al.[5]

ovum-sperm transfer in this light, comparing it with superovulation and insemination, gamete intrafallopian transfer, in vitro fertilization, and zygote intrafallopian transfer.

Peritoneal ovum-sperm transfer is less expensive than gamete or zygote intrafallopian transfer, which require laparoscopy or laparotomy for transfer. In my institution, peritoneal ovum-sperm transfer would be marginally less expensive than in vitro fertilization with uterine transfer, and more expensive than superovulation and insemination. Similarly, it is safer than gamete or zygote intrafallopian transfer, equivalent to in vitro fertilization, and riskier than superovulation and insemination, assuming an equivalent risk of hyperstimulation syndrome.

Efficacy is difficult to compare. In their definition of unexplained infertility, the authors have omitted evaluation of cervical mucus, sperm transport, and immunologic factors. Since other authors exclude couples with such abnormalities from the definition of unexplained infertility, across-the-board comparison with other series is unfair. Table I presents data from other publications on the pregnancy rate from superovulation and insemination in couples with unexplained, cervical, or immunologic infertility. These series are heterogeneous and retrospective but demonstrate an overall pregnancy rate of 13.2% per cycle, not significantly different from that reported for peritoneal ovum-sperm transfer ($p > 0.05$). Peritoneal ovum-sperm transfer should have a marginal advantage over superovulation and insemination because the number and quality of oocytes presented to the tubes can be controlled.

A direct comparison with large gamete intrafallopian transfer or in vitro fertilization series (as presented by the authors) is not applicable because these procedures are reported without respect for their indications. Devroey et al.[5] reported on zygote intrafallopian transfer in patients with unexplained infertility (Table II). The pregnancy rate of 48% per cycle is not significantly greater than that reported for peritoneal ovum-sperm transfer. The ongoing pregnancy rate of 37% (20/54) is significantly greater than the 13% rate for peritoneal ovum-sperm transfer ($p < 0.05$). Zygote intrafallopian transfer also confirms oocyte fertilization, an important concern in patients with unexplained infertility. The future possibility of zygote transfer by transcervical cannulation may obviate the need for laparoscopy in these patients.

Could superovulation and insemination supplant peritoneal ovum-sperm transfer? The 342 couples undergoing gamete intrafallopian transfer at Woman's Hospital of Texas could be considered to have unexplained infertility or failure to conceive despite treatment of nonmale factor infertility. In 63 couples who had undergone three superovulation and insemination cycles without conception before doing gamete intrafallopian transfer, there were eight pregnancies (12.7%). In 279 couples who had not undergone superovulation and insemination, there were 75 pregnancies (26.7%) ($p < 0.05$). For this reason, I have recommended that couples in this category who failed to conceive after superovulation and insemination consider zygote intrafallopian transfer. I do not feel that gamete intrafallopian transfer is appropriate for these couples. Because the rationale is similar, I do not feel such couples would be good candidates for peritoneal ovum-sperm transfer.

I have several questions for the authors. What was the fate of supernumerary oocytes obtained? If they were fertilized at in vitro fertilization, was there any correlation between the fate of these sibling oocytes and pregnancy at peritoneal ovum-sperm transfer? In view of the increasing consumer concern about veracity of reporting and the 50% rate of spontaneous abortion in this series, would it not be better to emphasize viable or "take-home" pregnancy rates rather than overall clinical pregnancy rates?

A, Van Steirteghem AC. Zygote intrafallopian transfer as a successful treatment for unexplained infertility. Fertil Steril 1989;52:246.

Dr. Pon Jola Coney, Tucson, Arizona. In vitro fertilization and embryo transfer were developed to treat infertile patients with damaged or absent fallopian tubes. The technique also has been shown to be effective in patients with non–tubal factor infertility. In an effort to improve the results in treatment, other innovative procedures of assisted reproduction have been developed.

Gamete intrafallopian transfer is based on the assumption that transfer of oocytes and spermatozoa to the fallopian tube would provide the most optimal conditions for fertilization and early embryo growth, because this is the natural site for these early events.

Direct intraperitoneal sperm insemination is based on the assumption that sperm transport along the fallopian tube is abnormal.

Peritoneal ovum-sperm transfer is based on the assumption that oocyte release does not occur or that sperm transport also is defective.

There are now reports consisting of approximately 50 patients who have undergone direct intraperitoneal sperm insemination with a pregnancy rate of 25%. Including the present report, there are now approximately 21 patients who have undergone peritoneal ovum-sperm transfer with a pregnancy rate of 26%. As reported by the In Vitro Fertilization Registry, the pregnancy rate for gamete intrafallopian transfer has consistently remained 27%.

The problem with both direct intraperitoneal sperm insemination and peritoneal ovum-sperm transfer lies within the small number of patients treated and the lack of larger, prospective, randomized, controlled studies comparing gamete intrafallopian transfer, direct intraperitoneal sperm insemination, and peritoneal ovum-sperm transfer in patients with non–tubal factor infertility.

If the techniques are equally successful, direct intraperitoneal sperm insemination would offer advantages over peritoneal ovum-sperm transfer and gamete intrafallopian transfer, with the latter two procedures being reserved for patients with failure of direct intraperitoneal sperm insemination or who would receive gamete intrafallopian transfer as an incidental procedure when laparoscopy is indicated.

Potential problems with peritoneal ovum-sperm transfer

Heterotopic pregnancy. Heterotopic pregnancy (concomitant intrauterine and extrauterine pregnancy) experienced an incidence of 1 in 25,000 pregnancies until the number of superovulation and assisted reproductive procedures increased. Most recently, several reports demonstrate an increase in heterotopic pregnancy in patients undergoing superovulation, in vitro fertilization, and gamete intrafallopian transfer procedures to an incidence of 1 in 200. Is this a result of spontaneous fertilization of unrecovered oocytes? Is there embryo migration from uterus to tube or from tube to peritoneal cavity, and would this incidence further increase if we directly placed sperm and ova in the peritoneal cavity?

Antisperm antibodies. The authors have recently reported a lack of antisperm antibody production in 11 patients undergoing intraperitoneal insemination of sperm and ova. Livi et al. have reported on 58 patients who were treated with at least two cycles each of direct intraperitoneal sperm insemination; in 28% antisperm antibodies had developed. In approximately half of these patients the antibody detection was transient in nature. With these contradictory reports the question is not resolved as to whether intraperitoneal inoculation of washed spermatozoa is very likely to result in massive antigen stimulation activating immunity to spermatozoa.

Finally, the benefit of peritoneal ovum-sperm transport, as in direct intraperitoneal sperm insemination and gamete intrafallopian transfer, to this particular group of infertile patients remains to be established. Infertility evaluation, age distribution, response to stimulation, indications for treatment, and durationof infertility all influence the prognosis for pregnancy, notwithstanding semen quality. Treatment-independent infertility, particularly in unexplained infertility, has long been known to result in spontaneous pregnancy rates in the range of 30%.

In conclusion, this is a very interesting report that could have dramatic influence on the clinical management of non–tubal factor infertility and clearly merits further clinical study.

Dr. Antonio Scommegna, Chicago, Illinois. When new techniques are investigated, it is important to compare them with more established techniques. The technique reported was compared with the results obtained with in vitro fertilization and gamete intrafallopian transfer procedures as reported by the National In Vitro Fertilization Registry. Unfortunately, the Registry is a compendium of all registered pregnancies—rates are not clinic specific and such rates may vary from 0% to 40%.

In our institution, for instance, in vitro fertilization and gamete intrafallopian transfer give essentially similar results except for male factors. Therefore in most instances in vitro fertilization is preferable. My question is, what are the specific rates for in vitro fertilization and gamete intrafallopian transfer in Dr. Coulam's program?

Also, what are the multiple pregnancy rates in this study? Since most programs now use gonadotropin-releasing hormone down regulation of the pituitary, I wonder if Dr. Coulam has, or if she is going to have, a series where down regulation is used before stimulation. The results may improve significantly.

Dr. Coulam (Closing). I thank Dr. Coney, Dr. Grunert, and Dr. Scommegna for their kind comments. I'll answer them as follows.

Dr. Grunert pointed out a comparison of the peritoneal ovum-sperm transfer procedure results with the other procedures available, and I have summarized these for you. These are a compilation of the world's literature reports of these procedures in a 3 × 3 matrix. There are sperm, egg, and fertilized egg; you can put those things in three different places—the uterus, the tube, and the peritoneal cavity. As pointed out, the pregnancy rates go up as you go in this direction.

There doesn't seem to be much benefit between these in terms of statistical results. The advantage, of course, is that this is an office procedure that takes 30 minutes, with half the cost, and it lacks the risk; this compares with the 13% result just for the superovulation intrauterine insemination.

Dr. Grunert asked about the fate of the extra eggs, and there are two possible fates. One, the patient is given the option of combining peritoneal ovum-sperm transfer with in vitro fertilization, but many times this is not a good economic option for them because they chose peritoneal ovum-sperm transfer. In this particular instance, they have a second option of donating eggs to individuals who don't have eggs.

Dr. Coney asked about sperm antibodies. We had careful follow-up of all these patients at monthly intervals, and we are mostly convinced that we are not inducing the formation of circulating antibodies to sperm in those women.

Dr. Scommegna very appropriately asked how these results compare with the results in our own institution, and just as in his program, we don't do many gamete intrafallopian transfer procedures because of the necessity of a general anesthetic and an operative procedure. So I don't have the results to share with you, but I do have our in vitro fertilization results.

In the particular year that we collected these 13 peritoneal ovum-sperm transfers, we had a 17% pregnancy rate per cycle transferred, which is analogous to the Registry results.

Our multiple pregnancy rate is high. It is about 60% in the peritoneal ovum-sperm transfer procedure, and, yes, we do use gonadotropin-releasing hormone for our standard in vitro fertilization ovulation induction at this time. At the time the peritoneal ovum-sperm transfer study was begun, we were not using gonadotropin-releasing hormone routinely.

President Malinak. Dr. Coulam, what about the abortion rate?

Dr. Coulam. We had six pregnancies with six babies and three abortions. Two of those abortions were clinical abortions and one was subclinical.

Oral contraceptives and antithrombin III: Variations by dosage and ABO blood group

Ronald T. Burkman, MD,[a] **William R. Bell, MD,**[b] **Howard A. Zacur, MD, PhD,**[c] **and Allyn W. Kimball, PhD**[d]
Detroit, Michigan, and Baltimore, Maryland

A randomized clinical trial of oral contraceptives evaluated 67 women on a regimen of 50 μg ethinyl estradiol and 1.0 mg norethindrone, 61 women on a regimen of 35 μg ethinyl estradiol and 1.0 mg norethindrone, and 64 women on a regimen of 35 μg ethinyl estradiol and 0.5 mg norethindrone. ABO blood group type was determined in all women. At baseline and at 3, 6, and 9 months, plasma antithrombin III levels, by both an immunologic and an activity method, and selected plasma levels of the contraceptive steroids were measured. Antithrombin III levels for all oral contraceptive groups combined decreased from baseline by 19.7% and 28.8% for the immunologic and activity methods, respectively. Analysis of interrelationships among antithrombin III by activity method, oral contraceptive type, and ABO blood group showed larger declines in antithrombin III for type O women using the highest estrogen dose preparation (31.6%) and for non–type O women using the lowest progestin dose preparation (38.9%). Plasma levels of contraceptive steroids also were related to changes in the most extreme levels of antithrombin III. (AM J OBSTET GYNECOL 1991;164:1453-60.)

Key words: Oral contraceptives, antithrombin III, ABO blood group

A number of studies have established a relationship between oral contraceptive use and changes in antithrombin III levels.[1-7] In addition, several studies have examined changes in antithrombin III levels and their relationship to thromboembolism.[8-12] Most investigations have suggested that the estrogen component in oral contraceptives is responsible for changes in antithrombin III, although this point has not been fully evaluated, particularly with current low-dose oral contraceptives.[11, 13] Further, there have been no randomized clinical trials that have examined differences among oral contraceptive preparations relative to antithrombin III, nor have there been any studies that have examined dose relationships in any detail. Finally, analyses have been confined to examining mean changes, although earlier studies by our group suggest the "outlier" analyses (study of subjects at the extremes) may add useful information.[14]

The current study is part of a series of clinical experiments designed to examine the relationship between oral contraceptive use, changes over time of selected lipids and lipoproteins, and blood pressure, as well as antithrombin III, and various measurements of contraceptive steroid levels as determined in plasma. Separate reports have addressed changes in lipid and lipoprotein levels and the relationship of some of these changes to contraceptive steroid levels.[14, 15] Analysis of patterns of plasma levels of contraceptive steroids, using 24-hour curves, indicates that steroid levels 24 hours after ingestion of the last oral contraceptive tablet and the initial slope or change in plasma levels after ingestion of a subsequent tablet provide an estimate of the metabolic behavior of these steroids.[1, 4]

This article presents additional results of a randomized clinical trial of healthy, young women using three different types of oral contraceptives relative to changes in antithrombin III levels, determined immunologically and with an activity test, during a 9-month period. In addition, information is presented on the relationship between certain metabolic measurements of the contraceptive steroids and the changes found in antithrombin III. The role of ABO blood type, a potential risk factor for thromboembolism, was also examined in relation to oral contraceptive use and levels of antithrombin III.[16, 17] The data also were analyzed with an approach to identify subjects in an outlier status according to the specific antithrombin III measurement.

Material and methods

Previous publications by our group have outlined in detail the basic study design.[14, 15] At the patient's initial visit, a complete blood count, ABO blood typing, and

complete urinalysis were obtained. For the antithrombin III determination, after an overnight fast, venous blood was drawn into tubes containing 3.8% trisodium citrate. After immediate transport to the Johns Hopkins Coagulation Laboratory, plasma was prepared by centrifugation of the anticoagulated blood for 15 minutes at 3500 rpm at 4° C. Assays were performed within minutes after plasma preparation; all specimens were measured in duplicate. Two approaches were used to determine antithrombin III levels: an immunologic test and a test of activity level. Results were expressed as percent activity compared with similar determinations in a pool of 200 healthy blood donors. Subjects were sampled on at least two occasions, 48 hours apart.

The immunologic test involved assaying antithrombin III for its presence as an immunologic protein. Antithrombin III antigen as an immunologic protein was quantified according to the technique described by Weeks[18] and Laurell,[19] using monospecific antisera obtained from Behring Diagnostics (La Jolla). Normal range with this technique is 71% to 200% of that obtained in normal subjects. For the activity test, antithrombin III was quantified as a biologically functional protein by measuring its inhibitory effect on activated factor X (Xa), by means of a previously described technique.[20-22] The normal range for this approach is 55% to 100%.

Subjects were separated into one of the three oral contraceptive groups by computer-generated, restricted randomization at the time of the second set of baseline antithrombin III determinations. Cards identifying the assignment to one of the three oral contraceptive groups were placed into opaque envelopes. The oral contraceptives used in this study are commercially available and included: ethinyl estradiol 50 μg plus norethindrone 1 mg, ethinyl estradiol 35 μg plus norethindrone 1 mg, and ethinyl estradiol, 35 μg plus norethindrone 0.5 mg. At the time of the second antithrombin III determination, after blood was first obtained in the trisodium citrate tubes, about 15 ml of venous blood was placed into heparinized tubes and centrifuged to obtain plasma; levels of ethinyl estradiol and norethindrone were determined as described previously.[14] One hour after ingestion of the first oral contraceptive pill, levels of these contraceptive steroids were again determined.

During the third, sixth, and ninth oral contraceptive cycles, we again obtained venous blood for antithrombin III determination after an overnight fast. In addition, samples for plasma steroid levels also were obtained. Sampling was done on day 21 of the pill cycle, although there were rare exceptions to this rule because of logistic considerations. In addition, follow-up questionnnaires and abbreviated physical examinations, including blood pressure determinations as described, were completed at each visit.

Outlier status was defined separately for both measurements of antithrombin III. We arbitrarily chose baseline values below the 10th percentile for women in this study to define outlier status. The cutoff points determined from the baseline data also were used to define outlier status at the subsequent study intervals.

The 0-hour contraceptive steroid level corresponded to the level obtained before the ingestion of the first pill at the initiation of oral contraceptive use and to the levels determined 24 hours after ingestion of the pill for day 20 at the 3-, 6-, and 9-month intervals. The initial slope was calculated by means of this 0-hour level value and the level determined 1 hour after ingestion of the pill for day 21 (i.e., 1-hour level minus 0-hour level over the 1-hour time interval). Subjects did not always have sampling precisely at these intervals; therefore actual times were used in the calculation.

We used a variety of statistical techniques to analyze the resultant data, including t and χ^2 tests, split-plot repeated measures analysis of variance, multiple linear regression analysis, multiple logistic regression analysis, and correlational analysis. In addition, we developed a procedure called trichotomous regression for use in analyzing the change in percent outliers from baseline to 3, 6, or 9 months, which takes into account the paired nature of the data and permits the evaluation of independent variables.[14]

Results

From Oct. 1, 1985, through Oct. 15, 1987, 316 women were enrolled in the study. Forty-seven withdrew or were excluded after the initial interview and 18 were excluded or withdrew after the initial physical examination. Because of inconvenience, minor side effects, or failure to keep appointments, 35 women withdrew between the first pill cycle and the 3-month visit, 11 women withdrew between the 3- and 6-month visits, and 13 women withdrew between the 6- and 9-month visits. A total of 192 women completed the full 9-month study cycle and are included in the subsequent analyses.

After randomization into the three oral contraceptive groups, there were no significant differences in respect to age, weight, body mass, prior oral contraceptive use, gravidity or parity, race, menstrual pattern, marital status, cigarette smoking, exercise, diet, alcohol intake, and past severe illness. The 59 eligible women not completing the full study cycle did not vary significantly from the women completing the study, except they weighed an average 2.4 kg less ($p = 0.04$) than the study group. These women were evenly distributed among the three study groups. The mean age in each group was about 25 years, and the mean weight was about 61 kg. A more detailed analysis of the study group characteristics has been presented elsewhere.[14, 15]

The resultant randomization and subsequent with-

Table I. Mean percentages for antithrombin III at baseline and at 3, 6, and 9 months for all oral contraceptive groups combined*

	Baseline	*3 mo*	*6 mo*	*9 mo*
Immunologic method	121.58 ± 1.89	101.09 ± 1.78	98.75 ± 1.89	97.66 ± 2.00
Activity method	129.42 ± 1.50	105.68 ± 1.86	98.27 ± 2.19	92.14 ± 2.29

*Values are mean ± SE. $p < 0.0001$ by repeated-measures analysis of variance.

Table II. Mean percentage decrease in antithrombin III (activity method) by oral contraceptive type and ABO blood group*

Blood type	*No.*	*0-3 mo*	*0-6 mo*	*0-9 mo*	*Combined mean*
50 μg Ethinyl estradiol, 1.0 mg norethindrone					
O	31	25.7 ± 5.5	30.7 ± 5.7	38.4 ± 6.9	31.6
Non-O	36	21.8 ± 5.0	25.2 ± 6.2	29.0 ± 5.6	25.3
35 μg Ethinyl estradiol, 1.0 mg norethindrone					
O	25	23.6 ± 5.8	27.7 ± 6.0	31.1 ± 7.2	27.5
Non-O	36	16.4 ± 5.0	24.2 ± 5.0	48.1 ± 4.7	29.6
35 μg Ethinyl estradiol, 0.5 mg norethindrone					
O	23	24.8 ± 8.2	38.1 ± 7.1	25.2 ± 7.0	29.4
Non-O	40	30.6 ± 4.0	41.5 ± 5.1	44.5 ± 7.0	38.9

*Values are mean ± SE. $p = 0.012$ by repeated-measures analysis of variance for interaction between blood group and oral contraceptive type.

drawals resulted in study groups composed as follows: 50 μg ethinyl estradiol plus 1.0 mg norethindrone, 67 women; 35 μg ethinyl estradiol plus 1.0 mg norethindrone, 61 women; and 35 μg ethinyl estradiol plus 0.5 mg norethindrone, 64 women.

Table I describes the changes in antithrombin III values for both methods for the combined oral contraceptive groups over the 9-month study period. There were no statistically significant differences according to type of oral contraceptive preparation. Mean baseline antithrombin III values for the immunologic and activity determinations, respectively, by ABO blood group type were: type O, 120.4% and 126.5%; type A, 120.3% and 130.8%; type B, 122.2% and 127.5%; and type AB, 113.6% and 131.9%. Table II presents changes in antithrombin III by the activity method according to oral contraceptive type and whether ABO blood type was O or non-O. These effects persisted even when the data were adjusted for other possible covariables, such as baseline antithrombin III. A similar analysis using the immunologic method showed declines in each time interval but no significant differences among oral contraceptive preparations or according to ABO blood type.

A number of trends were also shown when the antithrombin III data and contraceptive steroid values were related to outlier status. For the immunologic method, change in 0-hour ethinyl estradiol over the 9-month study period was positively associated with outlier status ($p = 0.01$); that is, higher estrogen levels before a subject ingested her next contraceptive pill were associated with an increased likelihood that she would achieve outlier status for antithrombin III. Change in the initial slope of ethinyl estradiol from baseline to 3 months was negatively associated with outlier status ($p = 0.02$); that is, the greater the change in slope between the two time intervals, the less likely a subject achieved outlier status for antithrombin III. In addition, the baseline initial slope of norethindrone was also positively associated with change to outlier status ($p = 0.03$). Finally, the higher the baseline immunologic antithrombin III measurement, the more likely a subject was to achieve outlier status at 9 months ($p = 0.0002$). None of these findings were significantly affected by type of oral contraceptive preparation.

For the activity method, the baseline initial slope of ethinyl estradiol and change in initial slope of ethinyl estradiol over time were negatively associated with change to antithrombin III outlier status ($p = 0.04$ and $p = 0.01$, respectively); that is, higher initial slopes or greater changes in slope over time for ethinyl estradiol reduced the likelihood that subjects would eventually achieve outlier status. Finally, the higher the activity antithrombin III level at baseline, the more likely a subject was to achieve outlier status at any subsequent time interval ($p < 0.001$). As with the immunologic method, there were no statistically significant differences shown according to oral contraceptive type in these analyses.

Comment

Thromboembolism is the most frequent serious sequela of the cardiovascular system associated with oral contraceptive use.[11] Although recent data suggest that this sequela may be decreasing in frequency as a result of lower-dose preparations, the relative risk of thromboembolism among oral contraceptive users is still about threefold.[23] Numerous studies have been undertaken to try to explain this association on the basis of underlying changes in the coagulation system; however, results have varied and to date none have been predictive.[10]

Since a congenital deficiency of antithrombin III has been shown to be associated with a high frequency of thrombosis, much attention has been focused on evaluating it in oral contraceptive users.[8, 11] However, several points need to be kept in mind. First, plasma levels of antithrombin III range between 40% and 55% of normal in families in whom the congenital deficiency has been described. However, not all family members exhibit thrombosis with these levels; in fact, antithrombin III levels in such families are not very predictive of clotting risk.[8] Among individuals who do not have the congenital deficiency but who do have thromboembolism, one author[24] estimated that approximately 70% have decreased levels of antithrombin III before initiation of anticoagulant therapy. However, it should be noted that these levels primarily reflect consumption that is due to thrombus development rather than preexisting deficiency.

The technique by which antithrombin III is measured appears important. Serum measurements may not reflect the true status, since the test systems measure the inactivation of thrombin, not the quantity of antithrombin III.[10] For example, elevations of prothrombin (often seen in oral contraceptive users) can result in declines in antithrombin III levels when serum measurements are used. Most authors[10, 20] accordingly recommend measurement in plasma to avoid this problem. Finally, it has been suggested that both an immunologic method and an assay for activity be used to better evaluate the effect of oral contraceptives on antithrombin III.[10, 11] Immunologic assays estimate overall quantity of antithrombin III but not necessarily activity. For example, some assays have been shown to give positive results in the presence of inactive protein. Activity assays that are based on the inhibition of factor Xa are independent of the rate of factor Xa inhibition, are not affected by large amounts of heparin in the test plasma, and are independent of other naturally occurring plasma protease inhibitors.[10, 20]

ABO blood group has been shown to be associated with risk of thromboembolism.[11, 17] Specifically, individuals with type O blood who are using oral contraceptives appeared to be relatively protected, compared with individuals with other blood types in one collaborative study.[17] For example, the relative risk of thromboembolism for oral contraceptive users with non-O blood type as opposed to blood type O was 3.2. In addition, one study also showed that women with blood types other than O (particularly type A) had lower antithrombin III levels when measured by an immunologic method.[16] Therefore a potential explanation for the interrelationship between ABO blood type and oral contraceptive use relative to thromboembolism could be reduction in levels of antithrombin III.

This study examined these two potential risk factors for thromboembolism (i.e., levels of antithrombin III, ABO blood type) among oral contraceptive users according to dosage and metabolism of the contraceptive steroids. Similar to other published results, mean levels of antithrombin III decreased over the study interval from baseline levels by 19.7% and 28.8% for the immunologic and activity measurements, respectively.[1-7] In addition, the data presented in Table I also suggest that these values could continue to decline beyond the time interval of the current study. A similar trend has been observed in other studies as well.[1, 6] The significance of this finding is at best unclear. If antithrombin III values were to continue to fall and if low values in oral contraceptive users were related to thromboembolic risk, one might expect to see duration of use as a risk factor for thromboembolism. However, available epidemiologic data does not suggest that there is a duration effect for thromboembolism among oral contraceptive users.[11]

When baseline levels of antithrombin III were examined in relation to blood group type, there were no significant differences shown regardless of methodology. Therefore were were unable to confirm previous findings, although perhaps the sample sizes in our study were too small to fully investigate this particular point.

The data presented in Table II do suggest an interaction between blood group type and type of oral contraceptive. For example, it appears that women with type O blood who use the 50 μg estrogen preparation showed greater declines in antithrombin III levels than those with non-O blood or those receiving a 35 μg estrogen oral contraceptive containing the same dose of progestin, i.e., 1.0 mg norethindrone. In addition, women receiving the lowest dose of norethindrone, i.e., 0.5 mg, who were blood group type non-O also showed larger declines in antithrombin III. These differences were only shown with the activity method. Although prior literature has indicated that the degree of change in antithrombin III better correlates with estrogen dose, at least one study involving the progestin lynestrenol has shown decreased levels of antithrombin III.[13] However, the authors of that article suggested that the estrogenic biologic activity of that compound was responsible for its actions on antithrombin III. Although there is no clear explanation regarding the differences seen according to oral contraceptive type and blood group type in this study, there are some possibilities. These differences may mean that the estrogen or progestin component interacts differently with individuals with O or non-O blood group type through some mechanism that has yet to be defined. Alternatively, particularly when one examines the oral contraceptive containing 35 μg ethinyl estradiol and 0.5 mg norethindrone, when the doses in oral contraceptives achieve low levels, their effects on antithrombin III are minimal in comparison with other factors. Therefore for this particular oral contraceptive only the differences or activity related to blood type are operant. Obviously, confirmation with additional studies would be of importance.

The metabolic changes of the contraceptive steroids and change to outlier status have some areas of consistency. The change in initial slope of ethinyl estradiol was negatively associated with change to outlier status for both types of antithrombin III determinations. This finding suggests that rapid uptake of the estrogen in some way reduces the chance that an individual will show more marked declines in antithrombin III. For the immunologic method, a high 0-hour ethinyl estradiol level was correlated with change to outlier status, a finding somewhat supporting the contention that estrogen dose correlates with the degree of antithrombin III fall among oral contraceptive users. The correlation between high initial antithrombin III levels and subsequent change to outlier status is difficult to explain. It may mean that such individuals are more sensitive to the effects of contraceptive steroids or that antithrombin III is catabolized or more rapidly cleared from the blood.

The findings in this study suggest that interactions among potential risk factors for thromboembolism are complex. However, further detailed study of these risk factors could yield useful information that might provide a better understanding of the risk of these disorders among users of oral contraceptives. Although it is unlikely that screening all oral contraceptive users for thromboembolism with a coagulation factor study such as antithrombin III will ever prove practical or cost-effective because of the overall low risk of this problem, screening certain subgroups might be important. For example, in one study of former oral contraceptive users who had experienced a cerebrovascular accident, the presence of reduced antithrombin III levels and mitral valve prolapse was striking when these women were compared with a control group.[25] Thus an area of future investigation could be the determination of antithrombin III levels in women with mitral valve prolapse before and during oral contraceptive use to detect changes that might suggest increased risk of thromboembolic cerebrovascular morbidity.

Discussion

Dr. Dennis J. Lutz, Minot, North Dakota. After the general availability of oral contraceptives in the early 1960s, evidence rapidly accumulated suggesting that the "pill" had effects on health other than the prevention of unwanted pregnancy. The epidemiologic evaluation of oral contraceptives began with the issue of thromboembolic disease and has been greatly expanded during the past 30 years. In particular, antithrombin III was noted very early to diminish in women taking oral contraceptives. Because individuals with congenital antithrombin III deficiency have a strong tendency to thromboembolic disease and because low antithrombin III levels are frequently observed in patients with thromboembolic disease, the opportunity seemed obvious for a presumably neat and tidy area of scientific investigation.

In 1971 von Kaulla et al.[1] showed that 80 μg estrogen–containing oral contraceptives induced a depression of antithrombin III activity plus an acceleration of thrombin generation almost immediately within the first cycle of therapy. Since these changes were very similar to those observed in patients with chronic thromboembolic disease, it was suggested that of all the clotting changes induced by oral contraceptives the loss of antithrombin III activity may be the one of the most clinical significance.

By 1980 it was apparent that oral contraceptives containing 75 to 150 μg of estrogen appeared to decrease antithrombin III activity to a greater extent than did the 50 μg dosage, while most progestogens alone did not appear to alter antithrombin III activity. Quantitative levels of antithrombin III were also noted to be lower in women with non-O blood types. A decade ago Stadel[2] therefore questioned whether oral contraceptive use is accompanied by a critical decrease in antithrombin III activity more frequently in women of non-O blood types. Dr. Burkman and his colleagues are now trying to address this question as another decade begins.

This article is a continuation and elaboration of Dr. Burkman's efforts to define the relationship of oral contraceptives to several clinical and laboratory parameters over time. He has successfully demonstrated and confirmed that both immunologic and activity levels of antithrombin III decrease within 3 months of initiation of oral contraceptive therapy. Although immunologic levels declined and stabilized at the end of the 9-month study, the more clinically important activity levels were still decreasing at 9 months. Perhaps an extension of this study to include 12-, 15-, and 18-month data would have been more appropriate? Since there were no statistically significant differences according to the type of oral contraceptive preparation prescribed, can any conclusions be drawn regarding dosage of estrogen or progestogen? Is a similar study being considered for triphasic preparations that were not readily available when this study began in 1985 but which have today become the oral contraceptive of choice for most patients?

Burkman et al. were unable to confirm any difference in baseline antithrombin III levels on the basis of blood group type. Perhaps the study group was too small, as they suggested, or perhaps earlier reports are incorrect. The mean percentage decrease in antithrombin III activity by oral contraceptive type and ABO blood group is intriguing but still difficult to analyze, again because of the small sample size in each subgroup.

Dr. Burkman and his colleagues are to be congratulated on using the randomized trial approach and for expending considerable attention to techniques that accurately measure both the immunologic and activity levels of antithrombin III. This has not always been done in the past and probably accounts for much of the conflicting data in the literature. Above all, the unbelievable complexity of the human coagulation mechanism is highlighted by this article, which raises more questions than it answers.

Dr. Ramona I. Slupik, Chicago, Illinois. This article generates more questions than answers. The variety of potential risk factors for thromboembolic disease explored here makes for some difficulty in reaching a conclusion that is clinically applicable, as the authors have admitted.

The most critical questions here today are: (1) Is oral contraceptive use accompanied by a biologically significant decrease in antithrombin III to <50%? (2) Is this decrease more likely to occur in women with non-O type or with certain oral contraceptive formulations? There still seems to be no test or combination of tests that can reliably predict in which patient a thromboembolic event may develop in association with oral contraceptives.

A reduction in antithrombin III activity of ≥50% substantially increases the risk of overt venous thromboembolic disease, and a reduction of ≥20% can be predictive of subclinical venous thromboembolic conditions extensive enough to be detectable by iodine 125–fibrinogen uptake.[1]

Obviously sole use of decreased activity levels of antithrombin III in oral contraceptive users cannot adequately predict the chance that overt thromboembolic disease will develop. Even in families with congenital antithrombin III deficiency where levels fall below 50%, not all individuals demonstrate thromboembolic disease, although up to 85% of these individuals do have a thromboembolic event between the second and fourth decades, when oral contraceptive use would be most likely.[2] Furthermore, antithrombin III decrements of this extent were not documented in this study. α_2-Macroglobulin and α_1-antitrypsin levels, with their contradictory ability to inhibit both thrombin and plasmin, are increased in oral contraceptive users and may play a modulatory role here[3,4]; varying degrees of decreased plasminogen activator release also may be involved.[5] The degree to which the oral contraceptives influence levels of the anticoagulants plasma protein C and protein S is yet to be elucidated.[6]

The role of ABO blood type creates some fascinating confusion here. In women not using oral contraceptives the risk of idiopathic deep venous thromboembolic disease is twice as great in patients with type non-O versus those with type O,[7] which may be due in part to lower levels of factor IX (von Willebrand's factor) in type O patients.[8] In oral contraceptive users the increased risk of deep venous thrombosis for women with type non-O is threefold,[7] suggesting a genetic susceptibility to idiopathic deep venous thrombosis that is multiplied by oral contraceptives.

Another potential explanation for these differences in risk is the relatively lower antithrombin III levels seen in type non-O (specifically type A), as compared with type O.[9] These variations in baseline antithrombin III levels between blood-type groups were not borne out in the present study, and the authors admit that small sample size may be the reason. The reason that all baseline antithrombin III levels in this paper were >100% is also unclear, because the authors refer to a normal activity level as 55% to 100%. Likewise, the "normal" immunologic antithrombin III value of 71% to 200% is not explained by the references cited[10, 11]; methods used by our hematology research laboratory at Northwestern University ascribe a normal value as 71% to 110% (unpublished data). Do these elevated baseline antithrombin III levels seen here reflect a nonrandom population sampling?

Another question relates to the changes in antithrombin III levels in type O and non-O subjects, relative to the three different oral contraceptive preparations studied. If variations in deep venous thrombosis incidence with ABO blood group presume a genetic susceptibility, who the diverse response to the oral contraceptive formulations? Whereas we would have expected to see both groups of women do worse on the higher estrogen pill, we instead see the more significant drop in antithrombin III in the patients with blood type O, previously regarded as somehow protective. Furthermore, the non-O patient, traditionally considered to be at higher risk, especially at higher estrogen levels, has a greater drop in antithrombin III on the lower estrogen formulation and a still greater drop when the progestin also is decreased. Does the progestin exhibit some type of protective effect? Is it dose-related? Does the mechanism pertain to relative estrogenic procoagulant biologic activity[12]? Is the progestin effect significant only in non-O patients? (Even so, the type O individuals also fared better on the higher progestin pill.) Perhaps presenting Table II as a scatter diagram, with absolute antithrombin III values and serial decreases instead of mean percentage decreases, would provide more relevant information regarding the number of individuals in whom a clinically significant reduction in antithrombin III was reached.

I have some questions. Should a patient's blood type influence which oral contraceptive we prescribe for her? Determination of blood type is not unreasonable and is certainly more economically feasible than testing baseline antithrombin III, which would detect only individuals at risk because of hereditary antithrombin III deficiency, or 1 of 2000 to 1 of 20,000 patients.[2] However, because we know antithrombin III levels must decrease by ≥50% to be clinically significant, can we justify any testing on the basis of the minor decreases reported in this article? Or should we test only certain subgroups known to be at higher risk, such as those with a family history of thromboembolic disease?

Dr. James R. Scott, Salt Lake City, Utah. Congenital or acquired clotting abnormalities, whether antithrombin III, protein C, or lupus anticoagulant, are very rare. Are the decreases in antithrombin III as you describe actually clinically important? In other words, has it been shown that patients with decreased levels in this range have an increased incidence of thrombotic episodes? I didn't hear anything about the clinical characteristics of these patients. Did any have a history of thrombosis?

Dr. Burkman (Closing). I thank Dr. Lutz and Dr. Slupik for their comments, as well as those who commented from the floor. I think both of the formal discussants have pointed out the complexities of studying this issue. What we are trying to do is relate a measurement of some type of clotting or fibrinolytic factor to the occurrence of a clinical event.

In the case of oral contraceptive users, the type of event, thromboembolism, occurs roughly between 50 and 100 times per 100,000 users per year. Therefore, relative to the question raised from the floor, the likelihood of someone in a study group actually experiencing the event one is trying to predict is low; that is, as one might predict, no one in this study had thromboembolism.

As to the predictability of low levels of antithrombin III, Dr. Slupik pointed out that even in families with congenital deficits with values of 40% to 50% of normal, a sizable proportion of individuals within the families may, in fact, have low levels and still not experience thromboembolism. Therefore, even with congenital deficiency, antithrombin III levels are not highly predictive.

The problem I think we are facing is trying to identify some proxy for thromboembolism. It is probably a problem of trying to use values determined in the clotting or fibrinolytic system, when there is a third factor that is difficult to study, the surface where the clot occurs. For example, that is why the data relating some of the changes in antithrombin III in women with mitral valve prolapse seem interesting to me as a means of studying the role of this third factor.

In regard to some of the other questions raised, we have not repeated this study with triphasic preparations. Although it is not clear why we did not show baseline antithrombin III differences among blood groups, it may very well be related to the methods used to perform the measurements or the small sample sizes in this study. The question was raised as to why some of the baseline values were above normal. This could mean that for some reason the women recruited into this study were in some way different from the general population, or it may be that the pools of women used for deriving the normal values were somewhat different. In any event we thought that the changes over time were of greater importance then the absolute values. Should blood group type influence what oral contraceptive you prescribe for a patient? I do not think so. This study was intended to show a method that might be useful for developing a hypothesis or means of studying small subgroups of women at risk. However, for the larger population of oral contraceptive users, I don't think any of these techniques should be used at the present time.

Should cervical cytologic testing be augmented by cervicography or human papillomavirus deoxyribonucleic acid detection?

**Richard Reid, MD,[a] Mitchell D. Greenberg, MD,[a] Attila Lorincz, PhD,[b]

Eastwood, Australia*

Criticism of the Papanicolaou smear in the lay press and recent federal legislation regulating cytology laboratories indicate a need to reappraise cervical cancer screening programs. This study directly compares three potential screening tests, used alone or in combination. A total of 1012 women aged 18 to 35 years were screened by cytologic testing, cervicography, and hybridization for human papillomavirus deoxyribonucleic acid, with discrepancies being refereed by the last two authors. After findings from the entire lower genital tract were combined, 116 women (11.5%) showed definite clinical abnormalities (either exophytic vulvovaginal condylomas or cervical squamous intraepithelial lesions). Another 72 (7.2%) had positive Southern blot hybridizations without accompanying viral expression, yielding a cumulative frequency for established disease or latent infection of 18.6%. When associated vulvovaginal condylomas are disregarded, final groupings with regard to cervical pathologic classification were: 23 high-grade and 71 low-grade squamous intraepithelial lesions, 164 cases of equivocal atypia (34 of which had detectable human papillomavirus deoxyribonucleic acid), and 754 cases with negative results (38 of which had detectable human papillomavirus deoxyribonucleic acid). Cervical screening tests were compared principally by plotting increasingly liberal recall criteria onto receiver operating characteristic curves (i.e., graphs of true-positive results on the Y axis versus false-positive results on the X axis). Used individually, each screening test was valid, but none was substantially better than the others. No matter how liberal the recall criteria, no single test was able to detect all of the 23 definite precursors in this sample. Applying conventional recall criteria (i.e., high- or low-grade lesion suspected), cytologic testing alone detected 12 high-grade squamous intraepithelial lesions (52.2%), at a cost of having to perform colposcopy in 8.7% of the sample. Combining all three tests and setting the end point as just a high-positive result by at least one test, 19 high-grade squamous intraepithelial lesions (83%) were detected, with a recall of 7%. Optimal test performance (96% sensitivity, 4% recall) would have been attained by recalling all patients with high-grade cytologic results or positive cervicography results, plus any patients with low-grade morphologic atypia in which hybridization detected an oncogenic human papillomavirus type. Our conclusions are as follows: (1) Cytologic detection rates are markedly improved by a second or third test; (2) increased screening costs could be offset by not recalling patients with minor lesions with no apparent potential for progression. (Am J Obstet Gynecol 1991;164:1461-71.)

Key words: Cervical neoplasia, cytology, cervicography, HPV testing, cost-effectiveness

Screening tests are relatively simple procedures designed to separate well persons from those with a high probability of having the disease under study, so as to permit early diagnosis and treatment. Test validity is measured in terms of two reciprocal ratios: sensitivity (positivity in disease) and specificity (negativity in health). Since the distribution of healthy and diseased subjects generally overlaps, a single screening test can never be perfect.[1] Rather, the cutoff point must be adjusted to compromise between maximizing sensitivity, at the cost of recalling some healthy subjects (false-positive results), or maximizing specificity at the cost of overlooking some subjects with disease (false-negative results). Highest specificity is important (1) where the disease in question is serious but not readily treatable, (2) where knowledge as to absence of disease has important personal and public health values, and (3) where false-positive results have serious sequelae (e.g.,

screening for human immunodeficiency virus infection). Conversely, sensitivity is accentuated (1) when early stages of the disease are readily treatable, (2) when missed diagnosis can squander the prospect of cure, and (3) when false-positive results do not create serious psychologic or economic hardship (e.g., colonic screening for occult blood). Since criteria for interpreting Papanicolaou smears were formulated in the precolposcopy era, at a time when a positive result led to cold knife conization and possible hysterectomy, cytologic cutoff points have favored specificity over sensitivity.[2] Adequacy of disease detection has traditionally relied on the likelihood of detecting false-negative cases at follow-up screening examinations, before progression to invasion cancer could occur.[3] However, widespread lay acceptance that cervical cancer is an avoidable disease has made apparent malfunction of the screening process a highly litigious area of gynecology.

In addition to being valid and acceptable, screening tests must also be justifiable on economic grounds. Cost/benefit ratio is generally measured in terms of the positive predictive value (the proportion of positive results that are true positive, after the test is applied to a population of both healthy and diseased subjects). Whereas sensitivity and specificity are constant for a given test, predictive values change dramatically according to disease prevalence within the screened population.[1] Since false-positive results always occur at a relatively constant rate, positive predictive value will either soar or plummet as the frequency of true-positive results rises or falls. Moreover, positive predictive value is more closely related to specificity (the ability to avoid false-positive results) than to sensitivity (avoidance of false-negative results). Therefore cost-effectiveness of cervical screening programs has been tied to the traditionally high specificity of the Papanicolaou smear. Introduction of the Bethesda terminology,[4] with its tendency to increase recall of patients with minor grade atypia, carries a risk of eroding the traditionally strong positive predictive value of an abnormal Papanicolaou smear.

After four decades of experience with exfoliative cytology, it seems doubtful that new advances can be secured by adaptations of the Papanicolaou smear alone. Rather, the best prospect of further reducing cervical cancer among screened women probably will depend on the incorporation of adjunctive measures such as cervicography or testing for human papillomavirus (HPV) infection. In that "oncogenic" HPV types are now incriminated as a cause of squamous intraepithelial lesions that may progress to cervical cancer,[5] viral testing would appear to hold considerable promise. Alternatively, even if the apparently causal association between "oncogenic" HPV infection and cervical neoplasia should subsequently be disproved, the strength and specificity of this association would still point to HPV detection as having valuable potential as a "surrogate" test.[6] However, to date, the clinical value of testing for the simple presence of HPV deoxyribonucleic acid (DNA) has been clouded by the fact that in 10% to 25% of apparently healthy women, these agents are exfoliated in morphologically normal cells.[7,8]

Whether such latent infections demarcate a large "at risk" pool or simply represent colonization of individuals who are not presently susceptible to disease expression remains an open issue. Even if it is accepted that testing for HPV DNA will not function as a useful primary detection tool, there is still a good possibility that HPV testing of minor grade lesions might perform well as an intermediate triage strategy.[9] Likewise, although formal colposcopic examination is too laborious for use as a rapid screening test, a modification of this technique by means of the cerviscope camera solves the logistic difficulties confronting screening colposcopy.[10] Hence this study was designed to compare available screening tests in a high-risk population, to examine type-specific viral associations, to approximate the prevalence of HPV exposure in both high- and low-risk groups, and to explore new options for improved cervical screening. Data analysis has centered primarily on using these data as a theoretic screening model, within which the practical consequences of different diagnostic decisions can be weighed.

Material and methods

Study design. This prospective survey examined the prevalence of lower genital tract HPV infection in a structured population of 1012 urban and suburban women aged 18 to 35 years, recruitment being undertaken in both a sexually transmitted disease (STD) clinic and private gynecologic offices. Patients were then screened for HPV infection and cervical intraepithelial neoplasia, by means of cytologic testing, cervicography, and DNA hybridization of exfoliated cells. The 298 women having an abnormal result by any one test were recalled for colposcopy and targeted biopsy. However, 68 of the subjects attending the clinic were either untraceable or unwilling to return for colposcopy. Since omitting these 68 women would have changed the balance between positive and negative screening test results, this group was retained under an assigned diagnosis.

Socioeconomic, clinicopathologic, and virologic results were entered into a computerized data base, cross checked for accuracy, and analyzed with the BMDP-88 statistical packages within an IBM386-2 microcomputer. Standard statistical differences were analyzed by the χ^2 test. Comparison of the different cervical screening tests was done principally by receiver operating characteristic curves, generated by plotting true-positive results on the Y axis and false-positive results on the X axis. Receiver operating characteristic curves have two major advantages. First, differing validities and efficiencies of multiple tests are compared graphically. "Useful" tests produce a linear plot with a slope of 45 degrees ("coin flip"), "perfect" tests produce a horizontal linear plot originating from 1.0 on the Y axis, and real-life tests produce curved plots lying within the upper left triangle (formed between the plots for a "useless" and a "perfect" test). Quality of test performance is judged by slope (vertical indicating good cost-effectiveness and horizontal indicating inefficiency) and proximity to the Y axis. Second, receiver operating characteristic curves allow ready visual comparison of the relationship between sensitivity and predictive value, as the cutoff points for any given test (or combination of tests) are variously restricted or liberalized.

Study population. The study population was drawn from two groups: a "high-risk" and a "low-risk" subset. The "high-risk" sample consisted of 672 volunteers attending Herman Keifer Clinic for Sexually Transmitted Diseases. The "low-risk" portion comprised 340 volunteers, recruited from four different gynecologic clinics to be more representative of affluent and less affluent women, both white and black (Fig. 1). Eligibility was restricted to patients aged 18 to 35 years, who had not presented for treatment of either cervical dysplasia or vulvar warts. Pregnant women, those who had undergone hysterectomy, and anyone taking immunosuppressant drugs were excluded. After informed consent was obtained, patients were interviewed for ascertainment of basic demographic and clinical information.

Median age was 24 years, and 621 (92%) were black. Distinct differences existed between sites of recruitment. Patients attending the STD clinic had the earliest median age of first intercourse, the highest lifetime number of sex partners, the highest median number of different sex partners per year of sexual activity, the highest proportion of Afro-Americans, and the highest proportion who reported a previous sexually transmitted infection (Table I). Hence, with regard to the intent to recruit subsets of women with differing levels of exposure to sexually transmitted infections, our sampling methods apparently achieved the study objectives of generating "high-risk" versus "low-risk" subsets. Demographics and sexual behavior reflected the heavy recruitment from the STD clinic. Of 999 respondents to questions on previous sexual behavior, 987 (98.8%) commenced coitus by age 20, and 819 (82%) reported three or more lifetime sexual partners. When these two variables were combined for evaluation of the American Cancer Society's definition of the "risk of abnormal cervical cytology,"[11] only 17 individuals (1.7%) fell into the "low-risk" category.

Table I. Demographic, sexual, and socioeconomic differences between the "high-risk" and "low-risk" subsets within this sample of 1012 women

Variable of interest	*STD clinic*	*Routine gynecologic clinics*
Proportion of black patients	621 (92%)	115 (34%)
Proportion of college graduates	225 (33%)	149 (48%)
Median age at first intercourse (yr)	16	17
Median lifetime No. of sex partners	6	3
Median No. of sex partners per year	2	1
Previous STD history	225 (33%)	59 (17%)
TOTAL	672	340

Screening examination. After careful inspection of the external genitalia, the cervix was exposed with an unlubricated speculum, and appropriate microbiologic studies were obtained (wet mount and gonococcal cultures). Cytologic screening was done with a two-slide technique—collection of an endocervical sample with a Zelsmyr Cytobrush and an exocervical sample with a dagger spatula. Results were reported as high-grade positive (cervical intraepithelial neoplasia grade 2 or 3 or higher), low-grade positive (definitely abnormal, suggestive of well-developed koilocytotic atypia or cervical intraepithelial neoplasia grade 1), equivocal (minor dyskaryosis of uncertain significance), or negative (no features of HPV infection). All positive and equivocal smears, together with a 10% sample of normal ones, were examined independently by two cytopathologists (M.H. and A.B.J.). Any discrepancy between

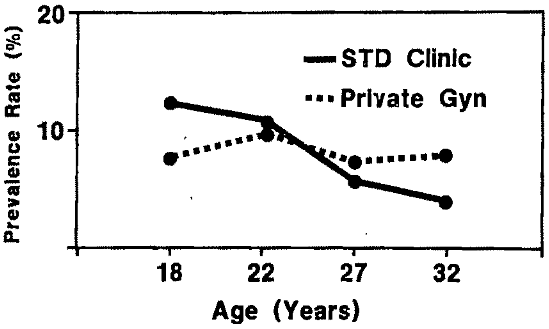

Fig. 2. Comparison of age-specific detection rates (for condyloma or cervical intraepithelial neoplasia), broken down by site of enrollment (*solid line*, STD clinic; *dashed line*, gynecology clinics).

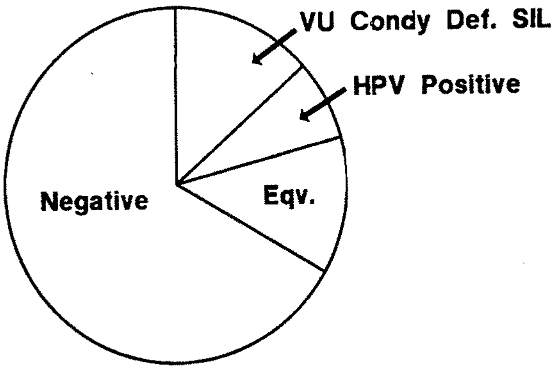

Fig. 3. Pie chart showing cumulative frequency of clinically expressed cervical or vulvar HPV-associated disease (11.5%), latent cervicovaginal HPV infection (18.6%), and the finding of an equivocal cervical screening test (30.7%) within this sample of 1012 women.

the paired cytopathologic opinions were adjudicated by a third cytopathologist (C.R.L.).

After the Papanicolaou smear was completed, the cervix was swabbed twice with 4% acetic acid and then photographed. Initially, photographs were taken with a standard camera fitted with bellows and a macrolens. However, resolution was poor and focus unreliable. The presence or absence of a lesion could be recognized, but grading was difficult. Hence after 3 months photography was done with a commercially available cerviscope, this being the best means of ensuring reproduction of the entire cervix, with minimal blur, excellent depth of field, and optimal color contrast between different tones of red. Images were interpreted by subsequent projection onto a 10-foot screen, with the observer standing at a distance of 3 feet. By this means, apparent magnification was comparable to the ×16 enlargement used during colposcopic examination. Results were reported in four categories: positive for a definite lesion showing high-grade features, positive for a definite lesion showing low-grade features, acetowhite change of uncertain significance, or negative.

The third screening method involved placing the residual cellular material from the Cytobrush and spatula within a special transport solution, for subsequent DNA extraction and Southern blot hybridization with radiolabeled probes for HPV types 6, 11, 16, 18, 31, 33, 35, 42, 43, 44, 45, 51, 52, and 56. Results were grouped as positive for an oncogenic type (HPV types 16, 18, 31, 33, 35, 45, 51, 52, and 56), positive for a low-risk type (HPV types 6, 11, 42, 43, and 44), positive for an unknown type, or negative.

Diagnostic evaluation of positive screening test results. The raw data were unexpectedly difficult to interpret, because of the following complexities: (1) Although the 343 definitely abnormal cervical test results (88 cytologic results, 135 cervigrams, and 120 hybridizations) were concentrated among 298 patients, the same clarity of demarcation did not hold for lesser degrees of atypia. Almost one third of the sample had an equivocal result by one or another of the screening tests. (2) Of the 298 patients to be recalled for colposcopy and directed biopsy, 68 were either untraceable or unwilling to return for diagnostic assessment. Since excluding this subset would have altered the balance between positive and negative screening patterns, these patients were retained and assigned to one of the diagnostic groups on the basis of the available information (Fig. 1). Such diagnoses were always conservative, with doubtful cases being downgraded to a lower category. Nonetheless, 17 women with definite abnormalities on a least two of the four examinations were classified as showing positive results: Three women were designated as having high-grade lesions and 14 as having low-grade lesions. Because the results of this study are mainly concerned with measuring how often the 23 high-grade lesions were either detected or missed by the various tests, the three women assigned to the high-grade category are the only ones with assumptions of any significance. The inclusion of 14 cases as low-grade lesions was of importance only in estimating the number of patients who, under conventional rules of diagnostic triage, would be recalled for biopsy and possible empiric therapy. (3) Even among those who had adequate assessment, 66 biopsy specimens showed histologic appearances that fell into the realm of nonspecific epithelial changes, rather than unequivocal koilocytotic atypia (Fig. 1). To avoid either overemphasizing or underemphasizing the importance of these equivocal histologic patterns, they were retained as a separate category that could be collapsed or maintained, according to the question of interest.

Results

Prevalence of HPV infection. After cervical and vulvar findings were combined, final status with regard to

Table II. Combined cervical, vaginal, and vulvar abnormalities among 1012 women

HPV status	*Category total*		*Cumulative count*	
	No.	*%*	*No.*	*%*
Vulvar condylomas* (possible cervical lesion)	31	3.1	31	3.1
Definite cervical lesion* (possible vulvar condylomas)	94	9.3	116	11.5
Positive HPV DNA but no definite lesion	72	7.1	188	18.6
Equivocal cytology/cervicography but negative HPV DNA hybridization	123	12.2	311	30.7
Negative by all tests	701	69.3	701	69.3
TOTAL	Categories not mutually exclusive*		1012	100

*Nine women with vulvar condylomas also had definite, low-grade squamous intraepithelial lesions of the cervix. Hence cumulative prevalence of expressed disease was 31 + 94 − 9 = 116.

HPV infection was as follows: 31 cases of exophytic vaginal or vulvar condyloma acuminatum (9 of these patients also had low-grade cervical lesions), 23 high-grade (cervical intraepithelial neoplasia grade 2 or higher) and 71 low-grade cervical squamous intraepithelial lesions (9 of these patients had vulvovaginal condylomas), 72 positive hybridizations without definite clinical expression, 123 equivocal cervical screening test results that were not confirmed by Southern blot hybridization, and 701 with negative results by all four examinations. If associated vulvovaginal condylomas are disregarded, morphologic findings with respect to cervical disease were: 23 high-grade squamous intraepithelial lesions, 71 low-grade squamous intraepithelial lesions, 164 equivocal cytologic or cervicographic screening test results (34 of these patients had detectable HPV DNA), and 754 morphologically normal cervices (38 of these patients had detectable HPV DNA).

Patients recruited at the STD clinic differed significantly with regard to age at first intercourse, lifetime number of sex partners, number of sexual partners per year, educational level, and income (Table I). Nonetheless, the only disease manifestation seen more frequently in the high-risk group was that exophytic vulvar condylomas were three times more common at the STD clinic (3.9% vs 1.5%). The age-specific detection rates for cervical condyloma or cervical intraepithelial neoplasia were the same for both subsets (Fig. 2). Moreover, within this sample there was no correlation between the sociosexual variables and either the frequency of cervical disease or the rate of HPV DNA detection. If it is assumed that all exophytic condylomas and all unequivocal cervical lesions are associated with HPV infection (even though HPV DNA detection rates presently approximate 95% and 90%, respectively[6]), then a minimum estimate of the extent of HPV exposure can be made (Table II). The detection of 31 external condylomas and 94 definite cervical lesions yielded a cumulative frequency for overt disease of 11.5% (Fig. 3). When the 72 women in whom HPV DNA was detected by Southern blot hybridization are added, despite the absence of a definite lower genital tract lesion, the minimal estimate of HPV colonization is 18.6%. Whether the remaining 123 (12.2%) patients with at least one positive morphologic screening test result represent HPV infection is an open question.

Type-specific HPV detection patterns. HPV DNA was detected by low-stringency Southern blot hybridization in 120 (11.8%) of these 1012 women. Type-specific detection rates are enumerated in Table III. Especially noteworthy is the detection of one of the "oncogenic" types in 55 (5.4%) subjects, including HPV 16 in 19 (1.9%), HPV 18 in 14 (1.4%), and HPV 31, 33, 35, 45, 51, 52, or 56 in 22 (2.2%). In contrast, HPVs 6, 11, 42, 43, and 44 were found relatively infrequently in these cervical swabbings. The fact that 43 of 120 (35.8%) positive hybridizations represented as yet uncharacterized genital types is also important. However, in that the vast majority of these unspecified types were detected within either minimal atypia or morphologically normal tissue, it appears that many of these HPVs may have little pathogenic potential (Fig. 4). In contrast to the unspecified group, a much larger proportion of the known HPV types did manifest cervical lesions showing well-developed morphologic evidence of viral cytopathic effect.

Performance of each screening test, used alone. With standard cytologic criteria, wherein any patient showing either a high-grade squamous intraepithelial lesion or a definite low-grade squamous intraepithelial lesion would be recalled for colposcopic workup, Papanicolaou smears detected 12 of the 23 high-grade lesions. Apart from disappointing accuracy (sensitivity 52%, specificity 92%), cytologic screening carried the significant disadvantage of recalling another 76 patients with either low-grade or borderline atypia (only 13 of

*Fifteen women had negative cytology, cervicography, and DNA tests, despite having exophytic vulvovaginal condylomas.

which contained some oncogenic HPV type). Attempts to reduce this high recall rate by restricting cutoff criteria to just those women with high-grade atypia led to a calamitous fall in sensitivity (35%). Conversely, attempts to make cytologic testing more sensitive by liberalizing the cutoff point to include women with atypia of uncertain significance led to the recall of 16.5% of patients, for the benefit of detecting just one additional high-grade lesion. Of course, in a real-life situation, some of the 11 patients with high-grade lesions that were missed by this single smear would have been recalled during the cytologic follow-up of equivocal atypia.

Used alone, cervicography and DNA hybridization each detected 14 of the 23 high-grade squamous intraepithelial lesions (61%), and both methods were verified to be valid screening tests when plotted on receiver operating characteristic curves (Fig. 5). However, neither was significantly better nor significantly worse than cytologic testing. Gains in sensitivity generally produced a loss in specificity. For example, combinations of cytologic testing plus hybridization raised sensitivity to 83% but reduced specificity to 88%.

Use of multiple screening tests. The sensitivity of cytologic testing was increased dramatically by the addition of either DNA hybridization or cervicography. However, unless recall was limited to those patients with just a high-grade abnormality by any of the screening tests, the combination of two tests produced an unrealistically high recall rate (20.3% for cytologic testing plus hybridization and 18.7% for cytologic testing plus cervicography). Better performance was obtained by using three tests in an attempt to reliably identify just the high-grade lesions (Fig. 6).

In our search for a solution to this problem, our model system suggested that we should designate a new end point, namely, the presence of either an established lesion or a potential precursor. Recalling those women who had a high-grade morphologic abnormality on either cytologic or cervicographic results irrespective of viral status and patients with minor grade aberrations containing an oncogenic HPV type detected 22 of 23 high-grade lesions (96%), at a cost of recalling only 3.5% of the population (that is, half of those recalled when cytologic testing was used) (Fig. 7).

The greater efficiency of the three-test regimen clearly offers the potential for cost savings (Fig. 8). If monetary values are assigned to the detection and treatment of just the prevalent squamous intraepithelial lesions (i.e., any future incidence of squamous intraepithelial lesions is ignored) ultimate expenditure during the first year of the extended screening program would approximate that of screening with just the Papanicolaou smear (Fig. 9). However, in subsequent years, the population screened by the extended regimen would contain only 4% false-negative results, for which triage and treatment costs would still have to be paid, compared with 48% false-negative results in the traditional cytologic program. Even without factoring in the enormous economic costs of having a proportion of false-negative cases progress to invasive cancer, the extended screening regimen would reduce costs by about one third.

Comment

The incidence of and mortality from cervical cancer have decreased steadily in developed Western countries since the 1950s. In Finland, population-based screening has reduced cervical cancer rates to 5.5 per 100,000 compared with 15.5 per 100,000 in Norway (without a nationwide program).[12, 13] In the United States age-adjusted mortality over the last decade has shown an overall decline of 18%.[14] However, mortality rates among women under age 45 remained stable during this period, while the incidence actually increased in this subset.[15] Moreover, modern screening programs are beset with logistic difficulties. There is considerable lay disillusionment over the high false negativity of Papanicolaou smears. Because of federal regulations limiting the number of slides that can be screened by each

cytotechnician, cytology laboratories now have difficulty in reading their assigned work load. Automated cytologic screening cannot yet fill this deficit. Colposcopic facilities are being overwhelmed by the large number of minor grade abnormalities being reported as "atypical," reflecting both a real increase in the prevalence of sexually transmitted HPV infections and a tendency toward liberalization of cytologic criteria. Maintaining or improving on screening benefits is likely to become increasingly difficult, as the birth cohorts who were teenagers and young adults during the "sexual revolution" approach menopause (the modal age for cervical cancer). For example, a careful analysis of 49 cervical cancers occurring in Rhode Island in 1987 showed that failure to attend for screening accounted for only 15% of cancers in women aged 20 to 39 years, compared with 65% of cancers in the 40 to 69 age group.[16] In contrast, 67% of the younger women had had a negative smear within 3 years of diagnosis, compared with 35% of the older group. Hence there is a need to critically reappraise traditional cervical screening practices, in terms of both what cutoff criteria are most suited to modern-day cytologic screening programs and what contribution might be expected from the incorporation of adjunctive tests.

Analysis of these 1012 women with known disease status suggests that exfoliative cytologic testing cannot be adapted to deliver improved sensitivity. Used as an isolated screening test (rather than as a series of examinations in a coordinated health care program), conventional cytologic criteria yielded a sensitivity of 52% and a specificity of 92%. Detecting 12 of the 23 high-grade squamous intraepithelial lesions in this data base required the recall of 8.7% of the screened population. Receiver operating characteristic curve analysis showed that more restricted cytologic cutoff points would markedly improve specificity but at a cost of a precipitate fall in sensitivity (52% to 35%). Conversely, liberalization of cytologic cutoff points seriously eroded specificity (92% to 84%) for a small gain in sensitivity (52% to 56%). Application of these liberalized criteria in routine clinical practice would have led to the recall of 16.5% of the screened population for the detection of only 13 of 23 known high-grade squamous intraepithelial lesions. Current trends to liberalize cytologic recall criteria, either in response to the introduction of the Bethesda terminology or as a hedge against poten-

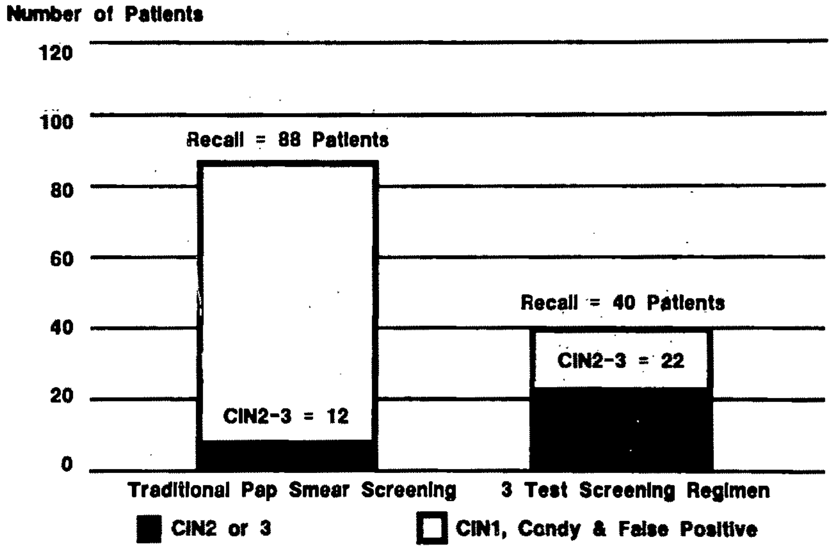

Fig. 8. Relative efficiencies of three-test regimen (40 recalls, detecting 22 cases of cervical intraepithelial neoplasia grade 2 or 3) versus the traditional Papanicolaou smear regimen (88 recalls, detecting 12 cases of cervical intraepithelial neoplasia grade 2 or 3).

Comparison of Projected Costs

CYTOLOGY ALONE (8.7% RECALL = 88 WOMEN)	
Initial screening visit $ ($40 x 1012)	40,480
Screening test cost ($25 x 1012)	25,300
Colposcopy & biopsy ($300 x 88)	26,400
Histology charges ($150 x 88)	13,200
Two colp. & cyto. follow-ups ($200 x 88 x 2)	35,200
	$140,580
Number of high grade SIL's detected	12
Cost per case	$11,715

3 TEST REGIMEN (4.0% RECALL = 40 WOMEN)	
Initial screening visit $ ($40 x 1012)	40,480
3 screening tests ($75 x 1012)	75,900
Colposcopy & biopsy ($300 x 40)	12,000
Histology charges ($150 x 40)	6,000
Two colp. & cyto. follow-ups ($200 x 40 x 2)	16,000
	$150,380
Number of high grade SIL's detected	22
Cost per case	$6,835

Fig. 9. Assigning monetary values shows that the extended screening regimen could produce savings of about 42% for each high-grade squamous intraepithelial lesion detection.

tial litigation, will produce a sharp decline in predictive value and place additional strain on existing diagnostic services. Hence this study suggests that traditional cytologic recall criteria represent the most advantageous compromise between sensitivity and specificity and that improved efficiency of a single screening examination will be achieved only by the addition of adjunctive measures.

Two potential adjunctive methods studied in direct comparison with cytologic testing proved to be independent and valid screening tests. Neither cervicography (sensitivity 61%, specificity 88%) nor DNA hybridization (sensitivity 61%, specificity 94%) was significantly better or significantly worse than exfoliative cytologic testing. Any simple combination of cytologic testing with either cervicography or DNA hybridization did improve sensitivity. However, both combinations tended to erode positive predictive values because of the relatively high incidence of both unsuspected acetowhite cervical epithelium and latent HPV infection in the general population. In contrast, combination of all three screening tests did allow the use of more restrictive criteria, such that one could recall only those patients with a high-grade abnormality by one or another test result, leading to a sensitivity of 83% and a recall cost of 7%. Even so, missing 17% of high-grade squamous intraepithelial lesions at any given screening examination is discomforting and carries an inevitable risk that a proportion of these false-negative cases might progress to invasive cancer during the screening interval.

Optimal sensitivity (96% sensitivity with 4% recall) required selection of a different group of end points; namely, (1) any high-grade cytologic or high-grade cervicographic lesion, irrespective of hybridization result, and (2) any low-grade morphologic atypia in which hybridization detected an oncogenic HPV type. Using this data base as a model system suggested that the additional costs of performing three screening tests could be offset by substantially reduced expenditure on diagnostic triage and empiric therapy.

In interpreting these results, the limitations of this data base must be borne in mind. First, this study was relatively small (1012 patients). Second, there was poor compliance from the STD population, many of whom gave false names and addresses and proved untraceable. Third, initial attempts at cervicography did not reach the proficiency attained in the last three quarters of the study. Finally, the measure of outcome was partly dependent on three cases in which histologic diagnosis was not available. This data base is not justification in itself for altering screening behavior; it simply outlines a provocative model that should be subjected to future testing. Any future decision to expand mass screening for cervical cancer should be supported by evidence from randomized clinical trials.

Discussion

DR. JOHN V. KNAUS, Evanston, Illinois. The Papanicolaou smear of cervical cytologic testing is actively undergoing the test of time and science—sensitivity, specificity, statistical analysis, and scrutiny in the literature. HPV is suddenly, and biologically, nearly inseparable from the Papanicolaou smear. Exfoliative cervical cytologic testing, as we have known it, will never be the same.

Dr. Reid and his colleagues pose the relatively high false-negative rate of the Papanicolaou smear as one of the critical issues involving cervical cytologic testing today. They examined cervical cytologic testing coupled with allied intermediate tests in an effort to improve cervical cytologic screening accuracy. The authors' results show neither cervicography nor HPV DNA hybridization alone to be significantly better or worse than cytologic testing alone. The addition of cervicography or HPV DNA hybridization to cytologic testing produced an unrealistically high patient recall rate. Use of all three tests in this model suggested establishing a different end point—the presence of either an established lesion or a potential precursor. This is an important point. The individual host tissue response to HPV exposure is extremely variable. As it should be, histologic confirmation of cytologically suspicious high-grade genital tract intraepithelial neoplasia is the standard on which therapy should be determined. Cost-ineffectiveness will remain until a screening test or tests materialize whose sensitivity and specificity improve the detection rate of clinically significant neoplastic precursors.

The authors offer us a beginning and evoke a series of questions that must be answered in the future. What will be the final resolution of the relatively high false-negative rate for a single screening cervical cytologic smear? Which tests will ultimately improve the failure rate for precursor lesion detection of 10% in patients with cervical cancer who have complied with regular cervical cytologic screening? When will assays with predictive value for reliable HPV detection be available? And finally how will the studies be achieved to reliably predict the spontaneous regression rate of the various HPV type–associated intraepithelial lower genital tract lesions?

Dr. Kenneth L. Noller, Worcester, Massachusetts. The detection of cervical cancer and its precursors always has been one of the primary missions of the gynecologist. With the widespread introduction of cervical cytologic screening in the mid 1950s, many believed that the ideal test for the detection of cervical neoplasia had been developed. However, as with so many of our technologies—continuous electronic fetal monitoring and routine obstetric ultrasonography, to name but two—it is only after widespread use that we begin to understand their limitations.

Unfortunately, few physicians fully understand the scientific basis for disease screening. First, and most important, no screening test ever identifies all cases of a disease. Just as there is never a single cause for any disease, so also is there never one screening method that will detect all individuals at risk for a given illness. The best we can achieve is to identify a subset of the population that is most likely to have or to develop the condition of interest. Indeed, the harder we try to be very specific and to identify all individuals at risk, the more likely we are to falsely assign normal persons to the potentially diseased category. Every screening test will fail to detect some diseased individuals.

Epidemiologists have developed measures for the predictability of screening tests. The four most useful measures are specificity, sensitivity, positive predictive value and negative predictive value. However, to develop a new screening test and to determine these values, it is necessary to know exactly how many individuals in the reference population have the disease of interest by some means other than the test being studied. Unfortunately, that number is unknown in studies of the type performed by Dr. Reid and his associates. The number of individuals with disease in this article was calculated by adding together those individuals found to have disease by the screening procedures under study. While it is difficult to perform a study any better than the way it was conducted by Dr. Reid, it is certainly not fair to apply the terms *specificity* and *sensitivity* to the results because the true number of individuals with disease is not known.

Many investigators are attempting to identify methods to increase the accuracy of Papanicolaou smears. We have a new, federally mandated cytology reporting system (the Bethesda System), a new method of screening (cervicography), and a myriad of ways to look for evidence of HPV infection. Yet all of these innovations have resulted only in causing more confusion. Dr. Reid's article helps to sort through this confusion a little by observing that multiple screening tests for the detection of cervical cancer precursors may more accurately identify those individuals at risk for disease, when compared with any one technique alone. Whereas I am not convinced that the authors have presented any meaningful data proving that their multiple test approach is cost-effective (indeed the comments regarding cost-effectiveness seem to be an afterthought), the results do suggest that it might be useful for us to consider screening individuals with multiple methods.

I do need to make one personal comment. I am tired of reading about, hearing about, and receiving from Papanicolaou smear laboratories, reports of "a few atypical squamous cells." It is time to remember that the purpose of cervical cancer screening is to detect cervical cancer and its precursors, not to diagnose infection. By far, the weight of evidence at the present time suggests that HPV infection and mild dysplasia are not cancer precursors in the vast majority of the patients in whom they are detected. Specifically, a given woman with an HPV infection or mild dysplasia has an almost zero probability that cervical cancer will ever develop, even if no treatment is performed. We have learned, and I hope everyone in this room has learned, that it is futile to attempt to treat asymptomatic HPV infection. In addition, pathologists and cytologists have confessed that they cannot differentiate HPV infection from mild dysplasia; indeed the new Bethesda System equates the two. To his credit, Dr. Reid has clearly identified patients with real disease (cervical intraepithelial neoplasia grades 2 and 3) from those with only minor cytologic and morphologic abnormalities of no significance.

I have only one question for Dr. Reid. Do you really believe that HPV DNA detection kits are clinically useful at the present time? The Centers for Disease Control and most HPV investigators have publically stated that they do not believe that these tests have any clinical relevance at the present time and should remain investigative.

Dr. Eduard Eichner, Cleveland, Ohio. Nobody has really said what I think is the biggest fault of Papanicolaou smears–that it the doctor who obtained them not fixing them properly or getting them stained eventually. In 1947 and 1948 I spent a little time with Dr. Papanicolaou. For several years I did my own tests until Dr. James Reagan came to Cleveland.

We found that there were laboratories that were giving us 100% false-positive or false-negative results, and the technicians were paid by the number of slides they analyzed per hour. They would process with no true vision, and the pathologist himself was not capable of reviewing what the report was. We finally got good pathologists who knew cytology and gave as close to 100% of a true report that we ever had in Cleveland.

Dr. Susan R. Johnson, Iowa City, Iowa. Perhaps I missed this in the presentation, but in the design of the study low-risk and high-risk women were nicely separated. However, I don't recall you saying whether the receiver operating characteristic curves from the two different risk groups were analyzed separately. Maybe the sample sizes were too small to do that. But in a day when insurance companies and others are trying to tell us to reduce Papanicolaou smear screening to every 3 years, these data would help determine if this is sometimes not appropriate. What do you think?

Dr. David V. Foley, Milwaukee, Wisconsin. I couldn't let this opportunity go by without mentioning the Milwaukee opinions. We are, of course, very involved in the cervicography studies and have found this a tremendous asset. I assure you that the money that Dr. Stafl gets from these photographs goes to our university, and we are very proud of that fact.

There is some problem with cervicography though. You have to learn how to use the camera properly and how to interpret the results properly; then I think we will have a definite adjunct to therapy.

One question is are you suggesting that this become a routine procedure in STD clinics and repeating it at yearly intervals? The cost can get out of hand if you do that sort of thing.

Dr. Reid (Closing). Dr. Knaus has asked if we can ever truly abolish the false-negative rate of the Papanicolaou smear. My answer is that I don't think that we can, principally because the Papanicolaou smear was constructed to favor specificity over sensitivity. In a similar vein, Dr. Eichner mentioned that the major contribution to laboratory error is failure by the clinician to adequately fix the glass slide before air drying can occur. Certainly, I agree with Dr. Eichner that if the clinician (or for that matter, the laboratory) does his job poorly, false-negative rates will balloon. However, I stress that the converse is not true. No matter how optimal the technique, false-negative results can never be abolished. For any single test screening regimen, the only realistic alternative to a high false-negative rate is reduced specificity and an unacceptably high false-positive rate. Unfortunately, the introduction of the Bethesda terminology is tending have this effect, thereby overloading colposcopic clinics to near breaking point.

The question was asked as to whether there is a single adjuvant screening test that would reliably abolish the problem of false-negative screenings. If I could look into the future, I would speculate that measuring HPV E6/E7 expression (the viral transforming genes) offers the best prospect of achieving this goal. Such an approach may soon become feasible, either by tests for exon-specific viral messenger ribonucleic acid production or by viral protein analysis. As to which of the presently available adjuvant tests will best detect an occult precursor lesion, I believe that the three-test combination offers the best strategy. If I had to pick just one adjuvant test, then I would choose cervicography in younger populations (where the transformation zone is usually visible on the cervical portio) and viral testing in older populations (where the disease can be wholly within the canal).

Dr. Noller has suggested that our data base does not have a valid "gold standard," against which to calculate sensitivity and specificity. Certainly, if Dr. Noller contends that we should have done a cone biopsy in all of the negative cases, then he is correct in maintaining that we lack such a "gold standard." However, ethics obviously preclude any such approach. If one reviews our methods, it will be clear that we come as close as is practicable to achieving a "gold standard." First, all but three of the patients with significantly positive results underwent colposcopy and biopsy. Second, we believe that patients who had normal results from physical examination, cytology, cervicography, and HPV testing can reasonably be accepted as "true negatives."

With regard to Dr. Noller's question as to what the Virapap offers, I agree that there are too many false-positive results with the kit as presently constituted. However, this is not to belittle the true achievements of this procedure. The Virapap is really a highly successful prototype that has replaced the slow, complex, highly specialized, poorly reproducible Southern blot with a quick, relatively cheap, highly reproducible alternative. Moreover, Virapap can be performed on batched (rather than single) samples, can be performed by a technician (rather than a scientist), and is available in nonspecialized laboratories through the use of a prepackaged kit.

As regards the practical value of Virapap today, this test would perform well as a part of the three-test model system described in our article. However, the mixture of viral probes in the existing Virapap kit is now obsolete and needs to be upgraded in the future. HPV 6/11 should be omitted from this screening kit, because we don't want to recall these patients for triage. Conversely, probes for more recently isolated oncogenic types (such as HPV 45, 51, 52, and 56) need to be included into the upgraded screening "cocktail."

Dr. Johnson asked if we have raw curves for the low- and high-risk populations. The answer is no, partly because only 1.7% satisfied the American Cancer Society's definition of women suited to screening every 3 years. However, the existing data did show a surprising similarity in the age-specific prevalence patterns between the groups recruited from STD and gynecology clinics.

Dr. Foley raised the question of how should we use cervicography. Certainly, both his experience and ours attest to the validity of this method. However, adding cytologic screening plus cervicography ad hoc can exacerbate the false-positive problem by increasing the need to recall a lot of patients with minor cervical lesions, of uncertain progressive potential.

The question of how often to screen a high-risk population is an important one. The data base presented here is only a model and does not allow us to calculate a final recommendation. For the future, diagnostic trials need to be undertaken, to allow quantification of the ideal screening interval.

Trends in the operative management of invasive squamous carcinoma of the vulva at Indiana University, 1974 to 1988

Gregory P. Sutton, MD, Margaret R. Miser, MD, Frederick B. Stehman, MD, Katherine Y. Look, MD, and Clarence E. Ehrlich, MD
Indianapolis, Indiana

From January 1974 to March 1988, 150 patients with primary invasive squamous cell carcinoma of the vulva underwent surgery at Indiana University. There has been a trend toward more conservative surgical management of this disease. To determine the impact of this trend on clinical outcome, cases were divided into three groups according to date of operation: group I, 1974 to 1978; group II, 1979 to 1983; and group III, 1984 to 1988. Overall, 80 patients had en bloc radical vulvectomy and groin dissection, 20 had modified radical vulvectomy and bilateral groin dissection through three separate incisions, and 36 had modified radical vulvectomy and unilateral superficial groin dissection. Fourteen patients had other operations. Forty-two patients (27.3%) had radiotherapy in addition to surgery. Among the three groups, there were no differences when mean age, International Federation of Gynecology and Obstetrics stage distribution (1988 system), mean lesion size, mean depth of invasion, or grade distribution were compared. A significant trend toward more conservative surgical therapy was observed. En bloc radical vulvectomy was performed in 77.4% of group I patients, 71.1% of group II patients, and 35.8% of group III patients ($p < 0.001$). Mean days of hospitalization were also reduced significantly. Group I had a mean stay of 30 days, group II had a mean stay of 23 days, and group III had a mean stay of 11 days ($p < 0.001$). Mean operative blood loss (group I, 754.8 ml; group II, 620.0 ml; group III, 393.6 ml; $p = 0.03$), mean units of blood transfused (group I, 1.4 units; group II, 1.3 units; group III, 0.4 units; $p < 0.01$), and mean hours of operating time (group I, 3.7 hours; group II, 3.7 hours; group III, 3.2 hours; $p = 0.02$) were also reduced. (AM J OBSTET GYNECOL 1991;164:1472-81.)

Key words: Squamous carcinoma of the vulva, groin dissection,

Radical vulvectomy with en bloc inguinofemoral lymphadenectomy was first introduced by Bassett[1] in 1912 and has been the standard treatment for invasive squamous carcinoma of the vulva for many years. The prolonged hospitalization and substantial morbidity associated with this operation have inspired many modifications. Taussig[2] suggested doing the operation through "... three incisions, one over each groin and one over the vulva, retaining a bridge of normal skin between them ...," and first Byron et al.[3] and later Hacker et al.[4] adopted this procedure with success. Brunschwig and Brockunier[5] advocated even more conservative therapy for "early" lesions, and other authors have helped to define the limits of such an operation. DiSaia et al.[6] successfully treated 18 patients with modified radical vulvectomy and superficial inguinal lymphadenectomy and prescribed this approach for patients with lesions of <1 cm in diameter and <5 mm in depth. During the last 15 years, these and other surgical modifications have been incorporated in the management of patients with vulvar carcinoma at Indiana University. This study was undertaken to determine what effect evolving operative techniques have had on the treatment of patients with invasive squamous carcinoma of the vulva.

Material and methods

Biopsy specimens confirming the diagnosis of invasive squamous carcinoma were reviewed in all cases by members of the Department of Pathology at Indiana University before surgical therapy.

En bloc radical vulvectomy and inguinofemoral lymphadenectomy were performed as described by Rutledge et al.[7] Primary closure was accomplished in nearly all cases. Radical vulvectomy and bilateral inguinofemoral lymphadenectomy through three incisions were performed as described by Hacker et al.,[4] except that the oblique groin incisions were rarely carried cephalad. The three-incision approach was not used in patients with clinically suspicious inguinal lymph nodes or with primary lesions extensive enough to risk inadequate margins if this technique was used.

Modified radical hemivulvectomy and ipsilateral superficial inguinal lymphadenectomy were used only if

6/6/28227

the primary lesion was ≤ 2 cm in diameter and invaded <5 mm into the underlying stroma. In addition, frozen section was used to evaluate the lymph nodes for metastases. If a midline lesion met these criteria, bilateral groin dissections were performed. The procedure was similar to that described by DiSaia et al.,[6] except that some patients underwent superficial femoral lymphadenectomy as well as inguinal lymphadenectomy. All patients had closed suction drainage of lymphadenectomy sites until daily drainage volume was <30 ml.

No specific attempt was made to determine either the depth of invasion or the adequacy of surgical margins at the time of primary surgery. Generally, a 2 cm margin around the clinically apparent lesion was obtained.

Before November 1977, patients with inguinal or femoral lymph node metastases underwent pelvic lymphadenectomy with postoperative inguinal and pelvic radiotherapy. From that date until July 1984, these patients were placed in a Gynecologic Oncology Group trial in which they were randomized between pelvic lymphadenectomy and radiotherapy. From July 1984, they were treated with postoperative radiotherapy without pelvic node dissection, unless resectable gross pelvic metastases were present.

Records were reviewed and the stage assigned retrospectively according to 1988 International Federation of Gynecology and Obstetrics (FIGO) classification for vulvar carcinoma (Table I). Where follow-up was incomplete, information was obtained by mailings to referring physicians or patients. Histologic evaluation was performed on formalin-fixed, paraffin-embedded 5 μm sections stained with hematoxylin and eosin.

Statistical comparison between groups was performed using the χ^2 test on True Epistat version 3.0 (Epistat Services, Richardson, Tex.). Survival and interval to recurrence was determined by Kaplan-Meier estimate, and intergroup survival comparisons were calculated by the Peto and Peto log-rank test with National Institutes of Health CLINFO software.

Results

From January 1974 to March 1988, 150 patients with primary invasive squamous carcinoma of the vulva underwent definitive surgery at Indiana University Medical Center. For comparison, patients were divided into three groups according to the date of surgery: Group I consisted of 31 patients undergoing surgery in 1974 through 1978, group II included 38 patients having surgery from 1979 through 1983, and group III was composed of 81 patients operated on in 1984 through 1988.

Eighty patients underwent en bloc radical vulvectomy and bilateral groin lymphadenectomy. Twenty patients had a radical vulvectomy and groin dissection performed through three incisions. Thirty-six patients underwent modified radical hemivulvectomy and superficial groin dissection for early lesions; 12 had bilateral groin dissection and 24 had a unilateral procedure. Fourteen patients had other procedures. These include 10 who underwent simple vulvectomy or wide local excision for lesions with ≤ 1 mm of stromal invasion, two who underwent radical vulvectomy without inguinal lymphadenectomy because of anesthetic risk, and one each who had anterior exenteration and laparotomy with paraaortic lymphadenectomy only.

Table I. 1988 FIGO staging classification for vulvar carcinoma

Stage 0	
TIS	Carcinoma in situ
Stage I	
T1N0M0	Tumor confined to vulva and/or perineum, ≤ 2 cm in greatest dimension
Stage II	
T2N0M0	Tumor confined to vulva and/or perineum, >2 cm in greatest dimension
Stage III	
T3N0M0 T3N1M0 T1N1M0 T2N1M0	Tumor of any size with: 1. Adjacent spread to lower urethra and/or vagina or anus, and/or 2. Unilateral regional lymph node metastasis
Stage IVA	
T1N2M0 T2N2M0 T3N2M0 T4, Any N, M0	Tumor invades any of the following: upper urethra, bladder mucosa, rectal mucosa, pelvic bone, and/or bilateral regional node metastasis
Stage IVB	
Any T, any N, M1	Any distant metastasis, including pelvic lymph nodes

Twenty-seven patients received postoperative radiation therapy to the pelvis and groins. Fifteen patients received other radiation therapy. There was no difference in the percentage of patients in each group who received radiotherapy. In group I, nine (29.0%) were treated, and in groups II and III, 12 (31.6%) and 21 (25.9%), respectively, received irradiation.

The age range of patients in this study was 26 to 89 years with a mean of 64. In groups I, II, and III the mean was 69, 68, and 63 years, respectively. Although patients in the third group were younger on the average, there was no significant age difference among the three groups ($p = 0.44$).

In all, 62 patients had FIGO stage I lesions, 44 had FIGO stage II disease, and 28 and 16, respectively, had stage III and IV tumors. Fig. 1 depicts the distribution of FIGO stages in the three groups of patients in this study. Stage I lesions occurred in 38.7%, 36.8%, and 44.4% of cases in sets I through III, respectively. There was no difference in the distribution of FIGO stages among the three groups ($p = 0.34$).

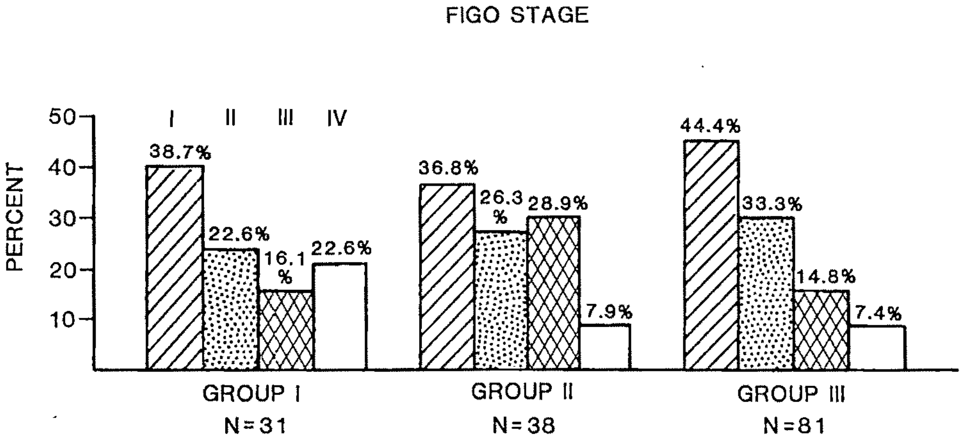

Fig. 1. FIGO stage distribution.

Table II. Recurrences and deaths—groups I and II

Patient	*Age (yr)*	*Stage*	*Recurrence (mo.)*	*Site*	*Therapy*	*Survival (mo.)*	*Status*
Group I							
L.J.	78	II	7.3	Vulva	Radiotherapy	12.2+	No evidence of disease
P.C.	81	II	10.3	Groin	Radiotherapy	10.3	Dead of disease
A.S.	63	III	18.9	Vulva, spine	Radiotherapy	21.8	Dead of disease
Z.A.	76	IV	—	—	—	4.0	Dead of disease
L.C.	54	IV	—	—	—	4.1	Dead of disease
C.W.	65	IV	—	—	—	11.5	Dead of disease
V.D.	83	IV	—	—	—	14	Dead of disease
Group II							
P.B.	89	II	6.9	Vulva	Surgery, radiotherapy	16.1	Dead of disease
M.F.	82	III	10.1	Vulva	Surgery	113.9+	No evidence of disease
C.K.	85	III	—	—	—	4.0	Dead of disease
A.N.	71	IV	—	—	—	1.7	Dead of disease

Overall, 84 patients (56%) had well-differentiated squamous carcinoma. Well-differentiated squamous carcinoma constituted 51.6%, 57.9%, and 56.8% of the populations, respectively, with no difference among the three groups.

Similarly, there was no appreciable difference when tumor size, whether measured by maximum diameter or by surface area, was compared among groups of patients. Diameters ranged from 0.4 to 12.0 cm with a study average of 2.7 cm. For the three subgroups, mean diameters were 2.8, 2.3, and 2.7 cm, respectively. Surface areas ranged from 0.2 to 65.0 cm^2, with means for the study and the three subsets of 9.3, 12.6, 7.3, and 9.1 cm^2, respectively.

The depth of stromal penetration of the tumors averaged 2.8 mm with a range of 0.2 to 8.0 mm with no differences among groups.

Thirty-six patients had metastases to inguinal lymph nodes. Bilateral metastases were present in 13 cases. The percentage of patients with lymph node metastases was greater in groups I and II (29% and 28.9%, respectively) than it was for group III (19.8%), but this difference was not significant.

Follow-up ranged from 1 to 156 months for all patients. Median follow-up was 11 months. There was no difference in median follow-up among the three groups.

The predominant type of operation varied significantly from group to group. Whereas 77.4% of patients in group I underwent en bloc radical vulvectomy and groin dissection, only 35.8% of patients in group III had this procedure. Similarly, no patient in group I had surgery through three incisions, but 19.8% of those in group III had this operation. The selection of operation demonstrated a significant trend from group I through group III ($p < 0.001$, Fig. 2). A significant reduction in operating time was also observed from group I to group III. In the first and second groups, mean time in the operating room was 3.7 hours. This was reduced to 3.2 hours in the third group of patients. Operating time decreased from 4.2 hours in patients undergoing en bloc radical vulvectomy to 3.2 hours and

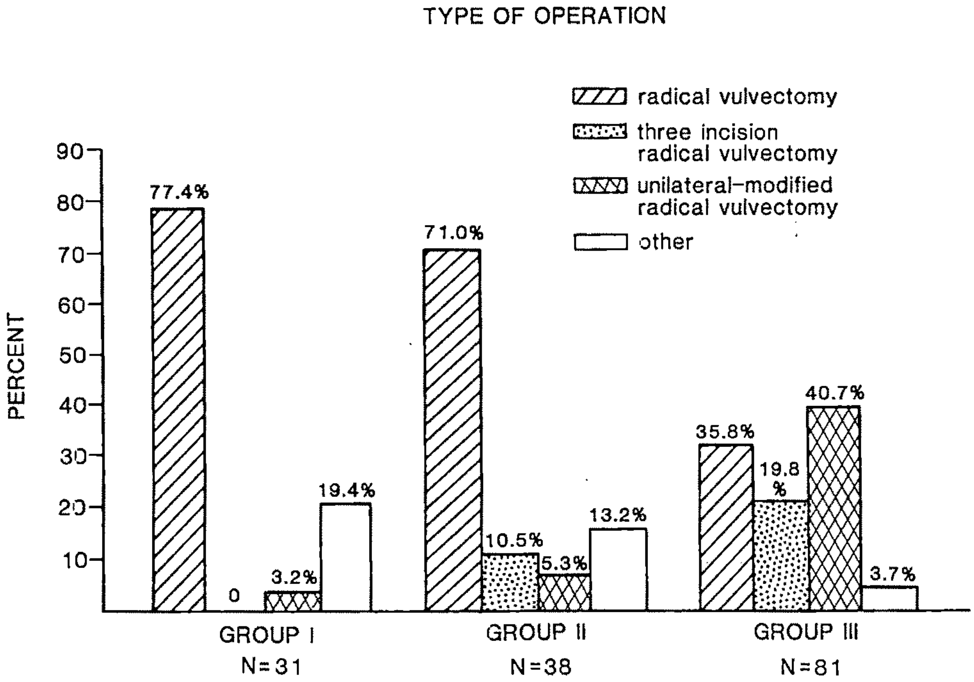

Fig. 2. Distribution of operation.

2.8 hours in those who had three-incision radical vulvectomies and modified hemivulvectomy and ipsilateral groin dissections, respectively. There was no significant difference in days of wound drainage among the three groups. Group I averaged 6.4 days drainage, group II 5.0 days, and group III 7.8 days ($p = 0.6$).

Blood loss and the number of units of blood transfused showed a downward trend, a result of more conservative surgery. In group I, the average blood loss was 754.8 ml (range, 100 to 2500 ml) and an average of 1.4 units (range, 0 to 4 units) was transfused. These averages decreased to 620.0 ml and 1.3 units in group II and 593.6 ml and 0.4 units in group III. The trend in blood loss is significant ($p = 0.03$) as is that for transfusion ($p < 0.01$). The decrease in blood loss and operating time in the three groups is a reflection of less extensive surgery. Patients who underwent radical vulvectomy lost an average of 714.2 ml (range, 150 to 2500 ml), compared with 389.5 ml (range, 140 to 1000 ml) for those who had radical vulvectomies through three incisions and 287.2 ml (range, 50 to 1500 ml) for those who had modified radical vulvectomies and unilateral groin dissections ($p = 0.001$).

Conservative surgery led to a significant decrease in length of hospitalization. The average hospital stay was 30 days (range, 7 to 86 days) in group I, 23 days (range, 3 to 55 days) in group II, and 11 days (range, 2 to 49 days) in group III. This trend is highly significant ($p < 0.001$).

There were a total of 21 recurrences in this study (14.0%). In group I four patients experienced recurrence from 7.0 to 16.0 months after operation, for a crude rate of 12.9%. In group II there were only two recurrences (5.3%) at 8.0 and 10.0 months after operation. The six recurrences in groups I and II were in patients belonging to stage II in three cases, stage III in two cases, and stage IV in one case. All followed en bloc surgery and were equally divided between vulvar and groin failures (Table II). In the third group there were 15 recurrences from 3.0 to 39.0 months after operation for a rate of 18.5%. In group III four patients who had conservative surgery for stage I disease suffered recurrences, all but one with a vulvar component (Table III). Additionally, in five patients with stage II disease and in three patients each with stage III and IV disease recurrent cancer developed. Eighty percent of the recurrences after operation for stage II through IV disease included a vulvar component. Only three of these patients had undergone en bloc surgery. Although the rate of recurrence was greater in group III, this difference failed to reach statistical significance (Fig. 3, $p = 0.077$).

There were eight recurrences involving the vulva or groin among 107 patients who underwent surgery alone. Among 26 patients who received postoperative radiotherapy to the pelvis and groin, two local recurrences were observed. Thus there was no obvious beneficial effect from radiotherapy among these patients.

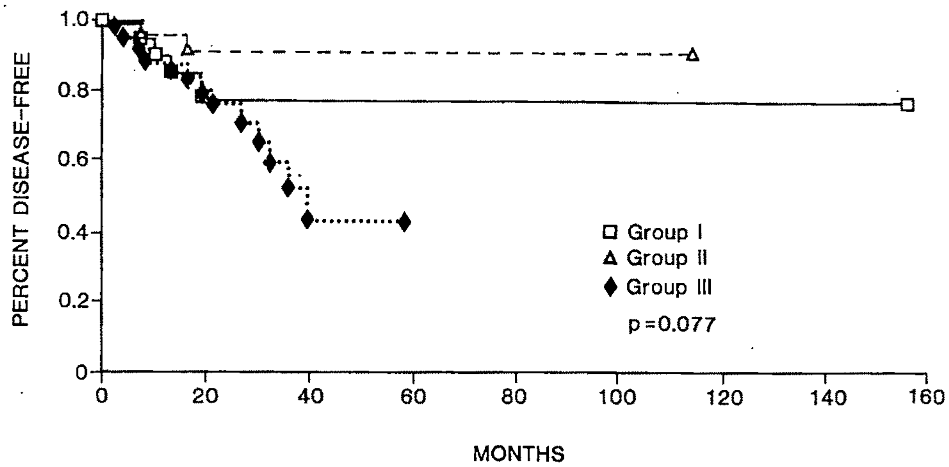

Fig. 3. Relapse-free survival versus group.

Table III. Recurrences and deaths—group III

Patient	*Age (yr)*	*Stage*	*Recurrence (mo.)*	*Site*	*Therapy*	*Survival (mo.)*	*Status*
E.R.	76	I	35.9	Vulva	Surgery	39.9+	No evidence of disease
M.M.	61	I	32.3	Vulva	Surgery	49.6+	No evidence of disease
D.B.	64	I	19.2	Vulva	Surgery	142.1+	No evidence of disease
D.M.	52	I	2.9	Vulva, groin	Surgery, radiotherapy	7.7	Dead of disease
D.R.	75	II	35.9	Vulva	Surgery	39.9+	No evidence of disease
V.A.	86	II	30.0	Vulva	Radiotherapy	30.0+	No evidence of disease
A.P.	72	II	21.0	Groin, lung	Chemotherapy	28.0+	Alive with disease
L.L.	72	II	24.0	Vulva	Surgery, radiotherapy	28.0+	No evidence of disease
D.V.	51	II	16.4	Groin	Chemotherapy	20.3	Dead of disease
E.T.	75	III	4.4	Groin	Radiotherapy	6.2+	Alive with disease
M.H.	68	III	4.3	Vulva	Chemotherapy	103	Dead of disease
M.P.	66	III	6.4	Vulva, groin	Chemotherapy	6.6	Dead of disease
H.H.	60	IV	2.6	Vulva, groin	Chemotherapy	5.6	Dead of disease
S.B.	34	IV	8.0	Vulva	Chemotherapy	8.0	Dead of disease
L.B.	83	IV	6.7	Vulva	Chemotherapy	8.0	Dead of disease

It should be noted that these numbers are too small for appropriate statistical analysis.

Eleven patients with recurrent cancer died of disease and two are alive with evidence of persistent carcinoma. In addition, there were five deaths among patients in groups I and II who were never rendered disease-free after diagnosis. The cancer-related mortality rate for this series of 150 patients is thus 10.7%. Crude survival rates among the three groups are 80.6%, 92.1%, and 91.3%. There were no statistical differences in survival rates among the three groups in this study ($p = 0.24$, Fig. 4).

Surgical complications occurred in 42.8% of cases and are listed in Table IV. In group I 55.1% had surgical complications, compared with 33.9% in group II and 41.5% in group III. There was no difference in complication rates among the three groups. However, the rate of surgical complications increased with increasing age. A surgical complication developed in only 16.7% of patients <30 years old. From ages 30 through 60 years, 33.7% had surgical complications, and over 60 years, 46.2% had surgical complications. Surgical complications decreased in the less extensive operations (Table V).

Comment

Bassett introduced the concept of en bloc radical vulvectomy and inguinofemoral lymphadenectomy for the treatment of carcinoma of the clitoris in 1912. Largely though the efforts of Stanley Way in England and Frederick Taussig in the United States, Bassett's operation became the standard of therapy in the treatment of vulvar malignancies. Both of these authors provided convincing arguments supporting extensive surgery. Plentyl and Friedman[8] summarized a number of surgical series and observed that survival rates improved from 30.8% with radical vulvectomy to 32.5% for radical vulvectomy with radiotherapy and from 55.7% with radical vulvectomy and groin lymphadenectomy to 63.2% when pelvic lymphadenectomy was

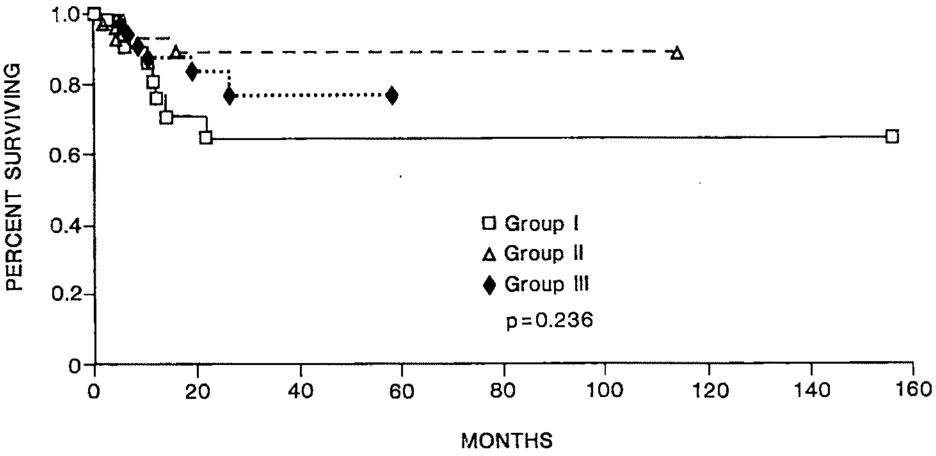

Fig. 4. Survival versus group.

added. Despite efforts to reduce surgical morbidity, such extensive operations are associated with wound complication rates that approach 60%.[9] Other problems such as chronic lymphedema and cellulitis also complicate these procedures.

Although Taussig suggested that radical vulvectomy and inguinal lymphadenectomy be performed through three separate incisions as early as 1940,[2] this concept was not well recognized in the modern surgical era until the publication by Byron et al.[3] in 1962. They advocated separate vertical incisions in the groins, sartorius muscle transposition, and postoperative suction catheter drainage. Ballon and Lamb[10] subsequently treated 18 patients with a similar technique. Most of these patients had primary healing of the groin incisions, and total hospitalization averaged 26 days.

In 1981 Hacker et al.[4] reported a series of 100 patients who underwent radical vulvectomy with the use of three incisions. The incidence of major wound breakdown was only 14%, and 38% of the patients in the series had primary healing of all wounds. Mean hospitalization was 19 days. Recurrent cancer developed in 16 patients. No isolated recurrence developed in the bridge of skin preserved between the groin and vulvar incisions in any patient, but skin-bridge recurrences developed in two in association with distant metastases. Each had positive inguinal lymph nodes.

The early definition and subsequent acceptance of microinvasive carcinoma of the cervix as a clinical entity has inspired a search for a "microinvasive" carcinoma of the vulva. Defining an early vulvar cancer should allow the performance of a conservative vulvar operation. Brunschwig and Brockunier[5] described a small group of patients with limited vulvar lesions who, for medical reasons, underwent local excision or modified vulvectomy. The cure rate in this group of patients was 66%; increasing lesion size was associated with greater risk of failure. In 1971, Franklin and Rutledge[11] reported inguinal metastases in only one of 18 patients with primary lesions measuring <1 cm in diameter and in 15% of 48 patients with lesions <2 cm in diameter. They noted no inguinal metastases in patients with invasive carcinoma arising in areas of carcinoma in situ if stromal invasion was <5 mm. In 1979 DiSaia et al.[6]

Table IV. Surgical complications in 187 patients with invasive vulvar carcinoma

Surgical complication	*No. of patients*
Wound separation	40
Lymphocyst	23
Wound infection-necrosis	14
Lymphedema	10
Hemorrhage-hematoma	7
Cellulitis	7
Lymphangitis	4
Osteomyelitis	3
Vaginal stenosis	2
Vulvar scar (requiring revision)	1
Vaginal fistula	1
Anal stricture	1

Table V. Type of operation compared with surgical complications in 187 patients with invasive vulvar carcinoma

Type of operation	*No. of patients*	*Surgical complications (%)*
Radical vulvectomy	100	56.0
Modified radical vulvectomy with bilateral groin dissection	22	54.5
Modified radical vulvectomy with unilateral groin dissection	39	23.1
Other	26	11.5
TOTAL	187	

reported a series of patient with squamous lesions confined to the vulva or perineum ≤ 1 cm in diameter with focal invasion of <5 mm. Surgery consisted of bilateral superficial inguinal lymphadenectomy and modified radical vulvectomy or hemivulvectomy. Only superficial inguinal and femoral lymph nodes were removed, the cribriform fascia being preserved intact. This approach does not involve the skeletonization of the femoral vessels, which lie below the cribriform fascia. Frozen section of the specimen was obtained and further lymph node surgery was not done in the absence of metastases in these superficial "sentinel" lymph nodes. Wide vulvar excision included a 3 cm margin of normal skin or mucosa surrounding the lesion, as well as adequate subcutaneous tissue, usually to the level of Colles' fascia. Eighteen patients so treated were doing well at 7 to 74 months (mean, 32 months) after operation. Two for whom this therapy was intended had metastases in the sentinel lymph nodes and were treated with standard radical vulvectomy with inguinal and ipsilateral pelvic lymphadenectomy.

The Gynecologic Oncology Group initiated a study in 1983 that involves modified radical hemivulvectomy and ipsilateral superficial inguinal lymphadenectomy with frozen section. Eligible patients are limited to FIGO stage I (tumor diameter <2 cm, clinically negative groin nodes), maximum tumor thickness of 5 mm, no vascular involvement, and surgical margins of 2 cm. Deep surgical margins of 1 cm are required. The inguinal dissection is essentially as described by DiSaia et al. If frozen section examination of the excised nodes reveals metastases, bilateral inguinofemoral lymphadenectomy in the traditional method is performed, and the patient may be a candidate for radiotherapy.

In this series the prescripts of Hacker and DiSaia were used in the treatment of patients with vulvar cancer. This retrospective series confirms the advantages of limited surgery: less time in the operating room, reduced blood loss and associated transfusion, and shortened hospital stay. The cost of these advantages may be an increased risk of local vulvar recurrence. Although such recurrences are usually amenable to surgical treatment or radiotherapy, they may be fatal. An increase in risk cannot be confirmed statistically in this series, but the observed trend is of concern.

The risk of local recurrence after conservative therapy has been reported by others. Burke et al.[12] observed a 10% rate of new or recurrent vulvar disease in a group of 32 patients with T1 or T2 lesions and clinically negative groin nodes managed by radical wide excision and selective lymphadenectomy. Heaps et al.[13] evaluated surgicopathologic features of vulvar cancer to predict recurrent disease. In their study the status of the surgical margin was the strongest indicator of risk for local recurrence. Six of seven patients with positive surgical margins and 21 of 44 patients (47.7%) with margins of <8 mm developed recurrent disease. In contrast, there were no local failures in 91 patients with free margins ≥ 8 mm. A clinicopathological evaluation of treatment failures in the present series is under way.

Discussion

DR. JOHN M. MALONE, JR., Detroit, Michigan. There are several criteria that I use in judging the merit of an article. Does it present new information or does it merely confirm what we already know? Are the design and analysis valid? Does it open new areas for investigation? And, finally, does it cause me to alter the way I practice? Dr. Sutton's timely study fulfills some of these criteria but not others.

This article reviews trends in the operative management of invasive vulvar cancer over 14 years at Indiana University and represents one of the first large, single-institution, retrospective studies, assessing the impact of less radical vulvar surgery on morbidity and survival.

The 150 patients are broken into three groups, covering roughly 5 years each. These groups are statistically similar in regard to mean age, stage, depth of penetration, and cellular differentiation. Over time, there was a trend toward less radical surgery. Of the group I patients, 77.4% underwent an en bloc radical vulvectomy and bilateral groin lymphadenectomy, whereas only 19.8% of the group III patients underwent this procedure, $p < 0.001$.

The authors detail the treatments rendered and their effect on measurable outcomes such as mean length of operating time and hospitalization, mean blood loss, and complication rates. Not surprisingly, these parameters all improved with time and fewer radical procedures. As far as effect on survival, the authors mentioned that no statistical difference was seen, $p = 0.77$. They quickly pointed out that even though no difference was seen, a trend was noted.

Recent trends in the therapy of vulvar cancer have been much like those in breast cancer; specifically, fewer radical procedures and more individualization of treatment. Intuitively, this is attractive. The central question, however, is in the quest for an improved quality of life. Have we sacrificed cures, and have we altered survival rates? The authors attempted to answer this question and did so partially; however, many questions were left unanswered and others were generated.

Some unanswered questions are as follows:

1. Mention is made of the use of adjunctive radiation therapy, yet no results are given. Does it help?
2. Mention is made of doing the lymphadenectomy through separate skin incisions. In light of recent reports of recurrence in the skin bridge, did the authors notice any recurrences in this area?[1]
3. As a practical matter, how does the operating surgeon ascertain whether there is ≥ 5 mm of invasion at the time of surgery?
4. Were the specimen margins checked for adequacy at the time of surgery? If not, does this account for any of the recurrences or are local recurrences evidence of the multifocal nature of this disease?
5. Most important, and the one question that I am interested in hearing an answer for today, is do the authors think that the trend toward less radical surgery is safe, or should we be going back to the more comprehensive and radical procedures first developed for this disease?

Finally, in the long run, the balance between care and quality of life is a delicate one and one we face every day. Perhaps the most valuable service that we can provide our patients is to understand the ramifications of treatment, explain them to the patient, and let her decide.

1. Schulz MJ, Penalver J. Recurrent vulvar carcinoma in the intervening tissue bridge in early invasive stage I disease treated by radical vulvectomy and bilateral groin dissection through separate incision. Gynecol Oncol 1989;35:383.

Dr. Robert D. Hilgers, Springfield, Illinois. This study analyzes 150 cases of squamous cell carcinoma of the vulva treated at The University of Indiana over a 14-year period from 1974 to 1988. The study design is based on three time periods set apart by the dates of surgery. Their results show that a change in the selection of surgical treatment occurred, first using the traditional en bloc radical vulvectomy and groin and pelvic lymphadenectomy and evolving to a more conservative modified radical vulvectomy and superficial node dissection for early carcinoma of the vulva and radiation therapy for treatment of positive groin nodes. Significant differences were noted not only in the selection of the type of operation but also in amount of blood loss, number of transfusions, and average hospital time as the operative procedure became more progressively conservative.

As a result the standard surgical treatment of squamous cell carcinoma of the vulva by radical vulvectomy and groin dissection has been replaced by more individualized treatment, occasionally preserving anatomic structure and function, without losing survival advantage in both early and advanced disease. What constitutes conservative operative management of the vulva and groin nodes and retaining a skin bridge, however, is not universally defined and agreed on, and the core of this presentation, i.e., the three major surgical procedures, as well as the radical wide local excision, may provide further clarification in each of these areas.

The first of these involves the vulva and the limits that can be safely applied without adding risk to the patient by preserving certain anatomic structures removed in the "type ordinaire" radical vulvectomy. In this regard, I wish to ask Dr. Sutton and his colleagues what is meant by a modified radical vulvectomy. The authors state that they had no vulvar recurrences in patients treated by radical vulvectomy and four vulvar recurrences in patients treated by modified radical vulvectomy and superficial inguinal lymphadenectomy in stage I disease. Is there any advantage of performing a modified radical vulvectomy or a radical wide local excision as opposed to a radical vulvectomy, and is the recurrence rate the same for a radical wide local excision or a radical hemivulvectomy as it is for a radical vulvectomy?

Second, the authors observed that the depth of stromal invasion ranged from 0.4 to 8 mm. Did the frequency of groin node metastasis increase with the depth of stromal invasion? Since the superficial inguinal nodes act as the first echelon of lymphatic spread in early squamous cell carcinoma of the vulva, are the superficial inguinal nodes sentinel nodes for predicting deeper nodal metastasis? Did the authors observe in any of their cases an instance where the superficial inguinal nodes were negative and the deep femoral nodes were positive for metastatic disease? Do they feel that there are different indicators for performing a superficial inguinal lymphadenectomy and an inguinal-femoral lymphadenectomy? Ordinarily, a difference in survival exists between patients with negative groin nodes and those with positive groin nodes. Did the authors notice any difference between these two subsets in their series?

Finally, what justifies leaving a skin bridge between the inguinal and the vulvar incisions, and what appears to be a safe recommendation for preserving the skin bridge in these patients?

Dr. James G. Blythe, St. Louis, Missouri. I've been watching in the literature the conservative movement in this field, and, if I understood your article correctly, my conclusion would be that using survival as an end point, as I move toward more conservative therapy it would remain the same.

However, using increased costs, it seems today that conservative therapy increases the recurrences and decreases the quality of care. Therefore my conclusion today would be that I had better look at conservative therapy very, very carefully in these patients and move slowly away from the radical surgery. I did not hear your conclusions. Could you share those, please?

Dr. Eduard Eichner, Cleveland, Ohio. A similar article was presented at the District 5 American College of Obstetricians and Gynecologists meeting in Toronto last week, in which the questions arose as to what was radical surgery, how you define it, and what you do. Since I had done pelvic lymphatic studies in the 1950s and reported them, I was asked to discuss this.

When we did our original vulvar studies, we found, with the usual dye studies, that in all our patients the femoral and inguinal lymphatic nodes were never involved because our patients were lying flat and motionless during the injection period.

We then followed a small injection of the dye as it went over the symphysis into the pelvis to the iliac area and followed the various pelvic lymphatic channels. We then put a small weight (½ to 1 ounce) bilaterally at the angle of the symphysis and then repeated the study on these patients; the dye never went over the symphysis. It went laterally through the femoral area first and then to the inguinal area, as well as the lateral thigh nodes; the only time dye that reached the iliacs was when the injection was made in the perirectal space at the inferior portion of the vulva.

Therefore at that time we started doing a modified Pfannenstiel incision and taking out internal nodes first when performing a vulvectomy. If Cloquet nodes were involved, it was said that the infection had gone deep into the pelvis, and these women all underwent a radical full vulvectomy.

If the femoral nodes were minimally involved or not involved, the incision was then extended to the superficial inguinals. If they were involved, radical surgery was done; if they were not involved, we just did a simple vulvectomy.

Dr. Karl C. Podratz, Rochester, Minnesota. Dr. Sutton, I you addressed the frequency of vulvar recurrence. I was wondering if you might share with us the site of these recurrences, that is, the central versus the lateral resected margins in the area that was resected. And also would you address whether there were contralateral recurrences in sites that were not operated on and the frequency with which you had recurrences in your cutaneous bridge?

Dr. Richard Reid, Southfield, Michigan. Again, I would like to ask Dr. Sutton about the vulvar recurrences. Was there a pattern to them? What were the preoperative surveillance methods used to detect insipid recurrence? Were any of them predictable preoperatively?

President Malinak, Houston, Texas. I would like to ask Dr. Sutton if, over the 14-year period, the differences in the intraoperative methods might have an influence on the difference in morbidity, such as more use of electrosurgical methods, the use of prophylactic antibiotics and that sort of thing?

Dr. Sutton (Closing). First of all, there obviously were changes in techniques over the years, and this study was naive to those changes and just looked at the time blocks. I am certain some of those techniques changed our operative parameters.

In the early part of the study, Dr. Ehrlich did most cases singlehandedly, and in later years he had a little bit of help. I think the number of people involved in the surgery probably affected its duration.

I agree with Dr. Blythe that we need to look critically at the conservative management of vulvar cancer. Not only our series but also Gynecologic Oncology Group series of conservative treatment have disclosed a number of recurrences. We noticed recurrences in the contralateral vulva. I think it really is important to consider the presence of vulvar dystrophy when the operation is planned. There were patients in this series who had a modified hemivulvectomy and had dystrophy in the remaining vulva. I think that that type of operation probably is not justified. I think if there is dystrophy in the contralateral vulva, a complete vulvectomy is indicated.

Dr. Podratz, we did not specifically look at sites of recurrences in terms of medial or lateral. We did look at vulva versus groin. We would have to go back to look at that data to get that information.

Dr. Reid, we had about four out of 36 patients in the third group who had recurrences after surgery for stage I lesions. All four of those patients had a vulvar component. One patient also had relapse in the groin. Interestingly enough, this patient had negative superficial inguinal lymph nodes at the time of operation. We didn't do many femoral node dissections, and when they were done, we didn't take pains to separate the femoral and inguinal specimens. Ideally, a study should be done that looks at that issue critically.

We have accepted the idea of sentinel nodes on the basis of a few studies of patients who did not experience relapse. We don't know that these are sentinel nodes, and I think it would be important to look at the superficial inguinal lymph nodes and the femoral lymph nodes separately.

Regarding the types of surgery, basically we took "wide local or wide radical incision" or "modified radical vulvectomy" to indicate that less than the whole vulva was excised. A radical vulvectomy was performed through three incisions or by en bloc technique, starting laterally at the labial-crural folds and removing the entire vulva.

Did we check the margins at the time of surgery? No, we did not. We attempted to get 2 to 3 cm of normal tissue at the margin of the specimen. I am not aware of any samples in the series that had positive margins at the initial operation.

The depth of invasion was determined on the preoperative biopsy specimen. We decided whether the patient could undergo a modified vulvectomy on the basis of this information. The final depth of invasion was determined on the pathologic specimen. We didn't experience skin bridge recurrences. Generally, if there are palpable or suspicious lymph nodes in the groin, we don't leave a skin bridge; if the lymph nodes are clinically negative, a skin bridge might be left.

I believe the recurrences that have been reported have been in patients who had palpable nodes in the groin.

Did radiation therapy help? We don't know. We didn't separate out those patients specifically, and that is obviously something we need to do.

The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation

**Isa Bernardini, MS,[a] Mark I. Evans, MD,[b] Kypros H. Nicolaides, MD,[c]
Demetrious L. Economides, MD,[c] and William A. Gahl, MD, PhD[a]**
Bethesda, Maryland, Detroit, Michigan, and London, England

In previous work we have shown, using cordocentesis to obtain fetal blood, that fetuses with intrauterine growth retardation are hypoxic and suffer from in utero starvation of nutrients. In this study we have developed gestational age curves for fetal blood amino acids and carnitine that now allow the development of a new parameter, the fetal concentrating index, which is the numeric mean of the fetal/maternal ratio of six essential and nonessential concentrated amino acids. Our data have shown that this index does not vary with gestation in either normal pregnancies (1.83 ± 0.42, mean ± SD) or pregnancies with intrauterine growth retardation (1.46 ± 0.38), but the index is markedly reduced in intrauterine growth retardation ($p < 0.001$). These results suggest that, because cordocentesis has become very safe in experienced hands, cordocentesis to obtain the fetal concentrating index might ethically be obtained in cases of fetuses at risk for intrauterine growth retardation, to devise strategies for intervention before the onset of severe hypoxia and morphometric changes. (AM J OBSTET GYNECOL 1991;164:1481-90.)

Key words: Fetal concentrating index, intrauterine growth retardation, amino acids, carnitine

In previous work we and others have measured maternal and fetal plasma amino acid concentrations.[1-3] These results have indicated that some amino acids, especially the essential ones, are concentrated in the human fetal circulation, whereas others are not.[3] The concentrating process requires energy, and causes of impaired energy production, e.g., starvation and placental insufficiency, reduce the capacity of the fetus to concentrate essential amino acids, such as valine.[1, 5] We specifically investigated the relationship of maternal and fetal amino acids in appropriate-for-gestational age

(AGA) and small-for-gestational-age (SGA) fetuses and found differences in the amino acid profiles between these groups.[3] The plasma fetal/maternal ratio of a compound indicates whether it is concentrated in the fetal circulation. A substance that is not concentrated has a ratio of approximately 1.0; a highly concentrated substance exhibits a ratio of 2.0 to 3.0. In SGA fetuses the ratio of essential, but not nonessential, amino acids correlated inversely with the changes in umbilical venous Po_2 of fetuses.[1]

Unfortunately, the gestational age variation in the fetal/maternal ratio differs markedly for every amino acid. Moreover, individual amino acids, or separating the essential ones from the nonessential ones, did not by themselves provide a means to prospectively assess impending growth retardation. Therefore we have extended our original observations to include carnitine, which is integral to mitochondrial fatty acid oxygenation and have developed a coordinated parameter, i.e., the fetal concentrating index, to describe quantitatively the ability of the placenta to extract circulating maternal amino acids. This index provides a more powerful measure of fetal concentrating ability than that offered by any single amino acid's fetal/maternal ratio.

Methods

Umbilical venous blood was obtained by cordocentesis at 16 to 36 weeks' gestation from 62 AGA fetuses and 31 SGA fetuses. In all cases gestational age was determined by Nägele's rule and confirmed by an ultrasonographic scan in early pregnancy. In both groups maternal blood was sampled from an antecubital vein immediately before cordocentesis. All the mothers were healthy, had negative screening results for antinuclear factor, and did not show serologic evidence of recent toxoplasmosis, rubella, cytomegalovirus, or syphilis infection. For 75 control pregnancies the indications were: prenatal diagnosis of blood disorders (*n* = 6), fetal infection (*n* = 3), α-antitrypsin disease (*n* = 1), elective termination (*n* = 4), karyotyping for amniotic fluid culture failure (*n* = 4), amniotic fluid mosaicism (*n* = 4), late booking (*n* = 4), and anatomic defects (*n* = 40). Patients with encephaloceles, hydrops, or chromosomal defects that could potentially alter amino acids were excluded from the control group.

Of the control pregnancies studied, 16 were terminated, and four were lost to follow-up. The remaining 55 were delivered at 34 to 40 weeks' gestation. Birth weights, available for 52 of these, were in every

case greater than the 5th percentile for gestational age.

The 38 patients in the SGA group were referred for fetal karyotyping and blood gas analysis because of ultrasonographic evidence of severe intrauterine growth retardation (IUGR). The fetal abdominal circumference was <25th percentile of our reference range, which was constructed from the study of 1610 normal pregnancies.[6,7] Three fetuses showed chromosomal abnormalities (one 47,XY +18 and two 69,XXX) and were excluded from this study. In 29 cases a subsequent birth weight was available, which helped confirm the diagnosis (birth weight ≤10th percentile). The gestational age at birth ranged from 22 to 39 weeks. The numbers of cases for differing measures vary somewhat because of the small volume of material available, sometimes requiring that some parameters not be analyzed on a given specimen.

Cordocentesis was performed as an outpatient procedure without maternal fasting or sedation or fetal paralysis and was achieved in every case. Fetal and maternal blood samples (300 μl) were collected in heparized syringes, placed into lithium-heparin tubes, and centrifuged for 10 minutes at 2000 rpm. The plasma was collected and stored at − 70° C. Plasma amino acids were measured with an LKB 4151 "alpha plus" amino acid analyzer (LKB Biochrom Ltd., Cambridge). The intraassay coefficient of variation was 6%.

A specific parameter, the fetal concentrating index, was devised to provide a measure of the overall concentrating ability of the fetus. Six normally concentrated amino acids (threonine, valine, methionine, tyrosine, phenylalanine, and lysine) were selected, and the numeric mean of their fetal/maternal ratios was calculated; this constitutes the fetal concentrating index. The choice of these six amino acids, including both essential and nonessential amino acids in which transplacental passage is mediated by differing mechanisms, is somewhat empiric. However, by using the amino acids that are normally the most concentrated and therefore presumably require the most energy for transport, we believe we can develop the system that is most likely to reflect energy changes in placental function.

Approval from the Hospital Ethics Committee was obtained both for the indication of cordocentesis and for the extra blood taken from mothers and fetuses for this study.

Results

Plasma amino acids from 75 normal control fetuses showed very little variation when grouped between 16

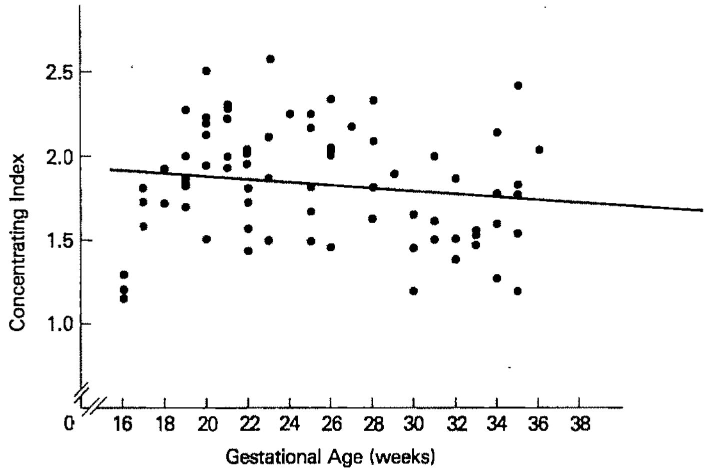

Fig. 1. Amino acid concentrating index as function of gestational age for 75 pregnancies with AGA fetuses. Concentrating index is defined in text. Regression line follows equation $y = -0.0086x + 2.05$. Its correlation coefficient was −0.15.

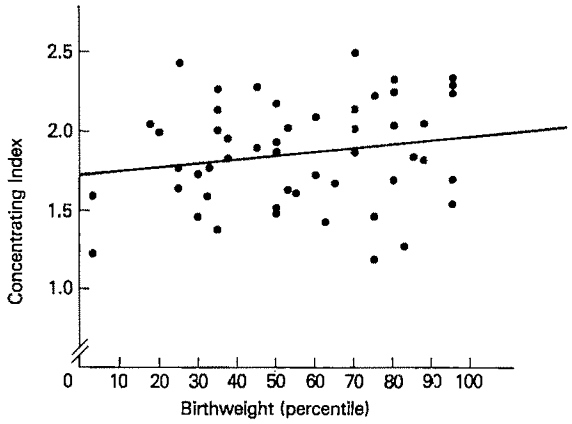

Fig. 2. Amino acid concentrating index as function of birth weight percentile for 51 pregnancies with AGA fetuses. Equation of regression line was $y = 0.0025x + 1.72$. Correlation coefficient was 0.19.

and 36 weeks' gestation (Table I). Two exceptions were asparagine, which was much lower in the second trimester than in the third trimester, and glutamine, whose mean plasma concentration fell with advancing gestational age. Fetal plasma free and total carnitine concentrations did not vary with gestational age (Table I).

Several essential amino acids such as threonine, valine, methionine, and lysine, as well as the presumably nonessential amino acids tyrosine, arginine, and ornithine, exhibited elevated fetal/maternal ratios in all gestational age groups (Table II). These amino acids are apparently concentrated by the fetus. Most nonessential amino acids, as well as free and total carnitine, are not concentrated in the fetal circulation. For most amino acids, as well as free and total carnitine, the fetal/maternal ratio did not vary with gestational age (Table II). The fetal/maternal ratio for valine, threonine, proline, and tyrosine decreased with advancing gestational age, whereas that for arginine increased.

With the fetal concentrating index, as defined in the Methods section, comparisons could be made between the growth-retarded and control fetuses. For normal control pregnancies the fetal concentrating index was 1.83 ± 0.42 (mean ± SD) and did not vary significantly with gestational age (Fig. 1) or birth weight percentile (Fig. 2).

To ascertain the potential contribution of mitochondrial fatty acid oxidation to energy production in developing fetuses, carnitine's concentrating ability was compared with amino acid's concentrating ability. Thus the fetal/maternal ratio of free carnitine was plotted against the fetal concentrating index for normal pregnancies (Fig. 3, *A*). If free carnitine were concentrated in the fetal circulation, a positive correlation would be expected. No such correlation was observed, indicating that the very same fetoplacental units that concentrated several amino acids nevertheless failed to concentrate free carnitine. There was also no correlation between the fetal/maternal ratio for free carnitine and the fetal concentrating index in 24 pregnancies with SGA fetuses (Fig. 3, *B*). Similar results were obtained when total rather than free carnitine ratios were studied in either AGA or SGA fetoplacental units (data not shown).

Pregnancies with AGA and SGA fetuses were

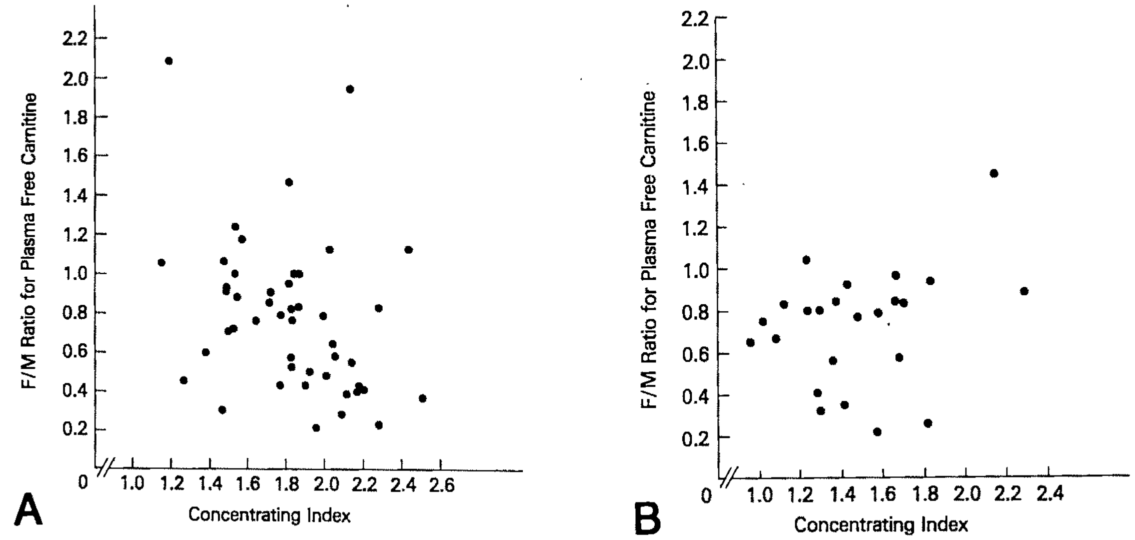

Fig. 3. Fetal/maternal ratio of plasma free carnitine plotted against concentrating index for 47 AGA (**A**) and 24 SGA (**B**) fetomaternal units. No correlation was noted for either group.

Table III. Fetal/maternal ratios of free and total carnitine concentrations and concentrating index for pregnancies with AGA and SGA fetuses

	AGA (mean ± SD)	*SGA (mean ± SD)*	*p**
Free carnitine fetal/maternal ratio	0.78 ± 0.37 (*n* = 45)	0.73 ± 0.27 (*n* = 24)	NS
Total carnitine fetal/maternal ratio	0.94 ± 0.25 (*n* = 19)	0.82 ± 0.23 (*n* = 14)	NS
Concentrating index	1.83 ± 0.42 (*n* = 74)	1.46 ± 0.38 (*n* = 41)	<0.001

NS, Not significant at $p = 0.05$.
*Two-tailed Student's *t* test.

grouped and compared with respect to their fetal/maternal ratios for amino acids and carnitine. Predictably, the ratios for free and total carnitine in pregnancies with SGA fetuses did not differ from normal ones (Table III). In contrast, however, the fetal concentrating index was significantly reduced in the pregnancies with SGA fetuses (1.46 ± 0.38), indicating impaired ability to concentrate certain amino acids in the IUGR fetuses. In fact, seven of 38 pregnancies with SGA fetuses had a fetal concentrating index <1.10, compared with none of 75 normal fetomaternal pairs (χ^2, 18.54; $p < 0.00001$). The fetal concentrating index for 38 pregnancies with SGA fetuses did not vary with gestational age (Fig. 4). A sensitivity of the fetal concentrating index for SGA fetuses was 100% with a specificity of 71%.

Comment

Previous expressions of fetal plasma amino acid concentrations have been in terms of a mean for 26 weeks' gestation and a slope to express variation with gestational age. Grouping by gestational age (Table I) allows ready determination of the normalcy or abnormalcy of an individual fetal amino acid concentration, determined at a particular gestational age, especially when the normal values change with gestational age. The grouping of fetal plasma amino acid values provides more accessible control values for comparison with those of fetuses at risk for aminoacidopathies and also can be used to monitor maternal dietary control in disorders such as phenylketonuria. The values also provide a reference table for comparison with amniotic fluid,[8, 9] cord blood,[8, 10] and plasma from infants,[8, 11] children,[8] and adults.[8, 12]

The fetal circulation does not concentrate carnitine, or β-hydroxy-δ-trimethylaminobutyric acid. This small molecule transports long-chain fatty acids into the mitochondria for oxidation to produce energy.[13] Apparently, the maternal concentration of free carnitine, which is lower than in nonpregnant women,[14-16] is sufficient to serve the fetal needs for fatty acid oxidation throughout pregnancy. In fact, no fetus with IUGR had a markedly decreased plasma carnitine level as a putative cause of growth retardation. The reason for re-

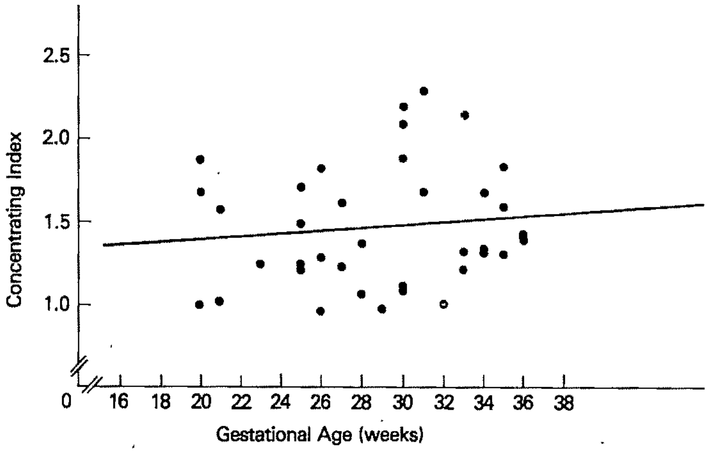

Fig. 4. Amino acid concentrating index as function of gestational age for 38 pregnancies with SGA fetuses. Regression line follows equation $y = 0.0091x + 1.195$. Correlation coefficient was 0.12.

duced maternal plasma carnitine in pregnancy remains enigmatic but may be related to an enhanced volume of distribution without increased hepatic synthesis or intestinal absorption of carnitine.

Our main focus, however, is the introduction of the fetal concentrating index as a more powerful measure of fetal amino acid's concentrating ability. Unlike measurements of individual amino acids that need to be adjusted for gestational age and as a whole do not differ between AGA and SGA fetuses, the fetal concentrating index is very significantly reduced in SGA fetuses compared with normal controls (Table III). Thus in the future the fetal concentrating index might be used as a quantitative gauge of the integrity of the fetoplacental unit when factors causing placental insufficiency are being investigated.

One major advantage of the fetal concentrating index is its gestational age independence; uncertainties about gestational age are rendered irrelevant. Furthermore, since a reduction can be observed even in early gestation in fetuses who develop IUGR, it may be possible to predict the cause of IUGR on the basis of this index. As cordocentesis has become very safe in experienced hands, it may now be ethical to use the fetal concentrating index to predict impending placental compromise, with consideration of early intervention in at-risk pregnancies. Amino acid determinations performed in an experienced laboratory and fetal concentrating index calculations can be offered in attempts to make this parameter part of a practical approach to IUGR diagnosis and potential intervention.

The choice of the six amino acids used in the fetal concentrating index is certainly arbitrary. Conceivably with more experience the choice, number, or relative weighing of components might change. Until a better understanding is obtained, we will continue to collect all parameters. Similarly, further work is needed to correlate these data with other diagnostic parameters such as biophysical and biochemical measurements.

Discussion

DR. JACQUES F. ROUX, Jackson, Wyoming. In the past 20 years maternal and fetal plasma amino acid profiles and concentrations have been determined in umbilical cord blood of normal deliveries and cesarean sections.[1, 2] In recent years, with the use of ultrasonography, cord blood is obtained in utero. This procedure is called cordocentesis or percutaneous blood sampling. It has to be noted that Cetin et al.[3] in 1988 and Economides et al.[4] in 1990 used a similar research protocol to determine amino acid concentration. They observed a decrease in amino acid concentration in the cord blood of SGA fetuses. Carnitine concentrations in fetal blood were measured, and no major comments need to be made about this substrate of fatty acid oxidation.

In this article the data have been broken down by gestational ages, including single amino acid concentration and fetal versus maternal level of amino acid. The results are expressed as a fetal/maternal ratio. When the ratio is >1, there is active transport of maternal amino acids to the fetal compartment. I have difficulty accepting some of the statements without a statistical evaluation of the data, especially those on asparagine and glutamine. Each standard deviation is very large and differs for each amino acid. This indicates that each substrate has its own metabolic pathway and that, the concentration differences not being significant among age groups, the data can be pooled. The authors should study one amino acid at a time in well-defined metabolic circumstances. For instance, asparagine and glutamine might be of interest since they show changes that seem to be statistically significant. Glutamine is the precursor of acetoacetate, a citric acid substrate, necessary to the Krebs cycle to provide energy to the fetal cells in the form of adenosine 5'-triphosphate. Asparagine, like alanine, goes to pyruvate and then to glucose and is a precursor of glycoprotein, a component of fetal membranes. Therefore the measurement of these two amino acids would provide interesting information on the fetal-placental unit, and the results might be more meaningful to the clinician than an indiscriminate screen of amino acids.

The present results are compared with maternal blood obtained in the upper extremity. The maternal concentration of amino acids could be misleading since muscles release various amounts of this substrate in response to food intake, amount of time after ingestion, and exercise. Furthermore, the circadian rhythm for amino acids is characterized by peak level, between 12 and 8 o'clock in the evening and between 4 and 8 o'clock in the morning.[5] These observations give little support to the use of brachial venous blood without a well-defined time of testing. Intervillous blood would be the best standard of comparison.

The computation of the fetal/maternal ratio indicates an active amino acid transport system. The large variability of the standard deviation of this ratio makes it difficult to interpret the data, except that the fetal/maternal ratio of valine, threonine, proline, and tyrosine decreases with advancing age, but there is no statistical study of the data. The results could be due to an increase in maternal amino acid concentration with gestational age. This would increase the denominator of the fetal/maternal fraction and produce a decreased ratio.

The authors stated that they had difficulty in developing a meaningful clinical test for amino acids. They decided to average the fetal/maternal ratio of six amino acids showing a high transport rate. They called it the fetal concentrating index. The idea was an excellent one, if one wanted to focus on transport and as long as one accepted that each amino acid has its own metabolic pathway, as is the case. The authors show that the fetal concentrating index for the SGA fetus is lower than that of the control. They then conclude that the SGA fetus has a deficiency in active placental transport of the six amino acids because of placental asphyxia. Two strong objections can be made to these statements. First, the difference between the fetal concentrating index means is 20%. Clinically this is meaningless because the statistical significance is mainly due to the number of determinations. Therefore, from the clinical point of view, it may be true that in a large population of SGA fetuses the fetal concentrating index will be low; however, on a case-to-case basis it will be difficult to consistently demonstrate a significant variation among samples. A normal physiologic variation can be as large as 15% to 20%. Second, in this clinical sampling one does not know how placental asphyxia was evaluated. In each case fetal acid-base status should have been determined and the data correlated with the fetal/maternal ratio. In this regard determinations on intervillous blood samples would be rewarding. Without this information the authors' conclusions are open to question because they are not verified empirically.

From a theoretical point of view the metabolism of amino acids supports the observations of the authors. In adults amino acids are transported actively through membranes by glutamyl transpeptidase.[6] This is an energy-dependent mechanism. Therefore a decreased fetal/maternal ratio could be explained by a lack of adenosine 5′-triphosphate generation, as a secondary result of a low Po_2.

In man, muscle releases alanine, which is transported to the liver, which converts it to glucose.[7, 8] Therefore, if the amino acid–glucose cycle is active in the placenta, a decrease in placental blood amino acid concentrations could reduce fetal amino acid availability. It is known that human placental tissue actively transports amino acids in vitro and in vivo. It uses them for its own metabolic needs and releases them in the fetal circulation. The mechanism of release was studied by Schneider et al.[9] He showed that placental tissue released only 26% to 47% of its amino acid content in an amino acid–free medium. It is then possible that the classic amino acid–glucose cycle observed in muscle and liver is different in the placenta. For instance, the decrease in amino acid level in the fetus could be due to a change in turnover of substrates in the fetal blood, the liver extracting a greater amount in the SGA fetus than in the normal fetus. Another possibility is that the SGA fetus releases less amino acid into the circulation from the placenta, muscle, and liver. This is independent of an abnormal amino acid transport. I strongly suggest to the authors that they expand their investigation to placental tissue and fetal-maternal blood obtained under ultrasonographic guidance. Blood glucose, pyruvate, amino acids, glucagon, insulin, and α-ketoglutarate concentration should be determined under controlled conditions to avoid biologic variations. These data should then be correlated with the maternal-fetal Po_2 and the acid-base balance in each case. A placental membrane preparation should be investigated for the presence of glutamyl transpeptidase in the SGA and normal fetus.

In the meantime, the present data interpretation is doubtful and the clinical applications are very limited. This study helps us to formalize new work hypotheses and to have a set-of-data basis. It opens new vistas on fetal biochemistry, a field that has been somewhat neglected in the last 10 to 15 years.

DR. RALPH K. TAMURA, Chicago, Illinois. With this study Bernardini et al. are extending and elaborating on significant prior work done in this area. Having previously published data on fetal plasma amino acid profiles in SGA and AGA fetuses, they now report on the usefulness of adding carnitine levels, and they have developed a coordinated parameter that they refer to as the fetal concentrating index to quantitatively describe the ability of the placenta to extract circulating amino acids. It appears to me that the patient data used for this study are identical to those previously reported by the authors,[1, 2] except of course for carnitine levels and for the fetal concentrating index. The following are queries that hopefully may clarify and strengthen this paper:

1. For the control pregnancies studied, could the fetal disease in any way affect the amino acid levels of the umbilical venous blood?

2. Why were fetuses with encephaloceles, hydrops, or chromosomal defects excluded? What are fetal concentrating indexes in these fetuses?

3. Regarding the number of control pregnancies, 75 minus 20 (16 terminations, 4 lost to follow-up) equals 55, not 57.

4. Regarding the cordocentesis procedure, how many attempts were performed per patient to obtain an adequate sample?

5. Why are there 80 control fetuses in the Results section but 75 in the Methods section?

6. Should not mention of the fetal concentrating index be placed in the Methods section?

7. Have these investigators analyzed the effect of using different individual amino acids for different gestational ages? That is, might not a different set of amino acids improve the predictive value of the fetal concentrating index in different trimesters?

8. Why were ornithine and taurine (high fetal concentrating index values) not used as part of the fetal concentrating index?

9. In the Methods section, 31 SGA fetuses were studied. Why were there 38 SGA pregnancies in the Results section?

10. May we asume that, on the basis of the data provided, the predictive value of the fetal concentrating index for SGA fetuses is 7 of 38 (18%) with a fetal concentrating index cutoff value of 1.10? What are sensitivity and specificity values?

This is an extremely interesting study in which basic and clinical research appear to have coalesced hopefully to provide some meaningful insights into the understanding of IUGR and SGA fetuses. To be used as part of the clinical armamentarium, however, correlations will need to be made between the fetal concentrating index and other antenatal diagnostic tests (i.e., biophysical profile, nonstress testing, and Doppler velocimetry, all of which are noninvasive).

DR. KENNETH J. MOISE, JR., Houston, Texas. I was wondering if you tried to correlate the ultrasonographic weights with the fetal concentrating index, both in the normal population and in the IUGR population? You appeared to be talking about babies after they were born as being ranked in the 5th percentile. Was there any correlation between the fetal concentrating index and the actual ultrasonographic weight at the time of the fetal blood sampling and the same question for IUGR?

DR. RICHARD P. PERKINS, Omaha, Nebraska. I am trying to decide what the importance of this is. First, it depends on whether you are of the school of thought that to detect it very early is a good thing. If one pursues that logic to its conclusion, one would say that cordocentesis is a procedure that is essentially without risk in the most experienced hands, that the objective therefore is to do it at the earliest point possible, and that we should have all of our cordocenteses done by only one person.

DR. CHIN-CHU LIN, Chicago, Illinois. I enjoyed the study very much. Briefly, in fetal growth retardation one of the mechanisms is thought to be a placental malfunction of the transport mechanism in the placenta for essential nutrients across the membranes.

My question is, have you made any correlation with the concentration of fetal-to-maternal rate gradient with respect to simple measures, such as placental morphologic type, either grossly or histologically?

DR. CHESTER B. MARTIN, Madison, Wisconsin. To follow up on the last question, were there any differences in an outcome variable between those SGA fetuses with a fetal concentrating index <1.1 and >1.1? And how many inadvertent or unplanned interventions were carried out as a consequence of the cordocentesis?

DR. PETER F. FEHR, St. Paul, Minnesota. One of the problems experienced with patients who had intravascular transfusions is fetal-maternal bleeding. I'm wondering if the authors measured these and whether they discovered, as our areas discovered, that synthesis is occurring in these patients at a higher rate than in the normal population. How would they justify this in terms of maternal informed consent before they do a cordocentesis in these patients?

DR. WILLIAM J. OTT, St. Louis, Missouri. I have a number of questions, but I will limit them to two. In your Methods section, how did you differentiate between the SGA infant who suffers from IUGR and those infants that are small for gestational age but are so because they are constitutionally small but otherwise totally normal? Second, how did you differentiate between the AGA fetuses whose birth weights may be above the 5th percentile but still have not met their inherent growth potential?

The second question deals with the clinical relevance of the study. Although cordocentesis may provide important biochemical data, it is an extremely operator-intense procedure. Our institution has been using the technique for approximately 2½ to 3 years, and we find that it significantly raises catecholamine levels in both the mother and the physician. I wonder whether the information obtained from cordocentesis provides any additional information over that obtained from noninvasive procedures, such as fetal heart rate monitoring or Doppler blood flow studies?

DR. EVANS (Closing). I thank all of the discussants and questioners for their thoughtful comnents.

Probably the most important concept I would like to reemphasize is that this is a pilot study. We felt it was necessary to do these determinations on patients who were having cordocentesis for other indications and use extra blood to see if we could define a parameter that would help us. I think we have to some degree.

I agree with Dr. Roux that there are a number of different possible explanations for the specific differences seen. It is also not clear that these six amino acids that we have chosen through our first pass will end up being the ultimate parameters that are used, if any, as this data set continues to go on. The major thing we tried to accomplish with this article was to show optimism that we might have a useful parameter and to make it ethically appropriate to attempt to study this prospectively.

None of the management of patients was affected by this, because these tests were conducted long after the pregnancies were concluded. As a matter of fact, they were run on different sides of the Atlantic from where the patients actually were, so it would be hard to have an exact intervention on the basis of the results.

In terms of what Dr. Roux said about where we draw the blood, it might be better scientifically to get the blood out of the femoral artery. I think politically it would be much less acceptable and much less likely to be allowed to be used.

Dr. Tamura, as far as numbers are concerned, obviously I'm not as good at the abacus as you are. There are a couple of differences mainly because we did not have all the data for some of the patients because there was a variable amount of blood available for running the 30 or so different parameters. So for some patients it turns out we had enough blood to run for the parameters that ultimately became the fetal concentrating index but not enough for other parameters.

A 1.1 cutoff was arbitrarily defined but did pick up, as Dr. Tamura said, in seven out of 38 cases. Whether that will be the ultimate cutoff will depend on how many more numbers are necessary to have an index.

As for Dr. Moise's question, the patients were categorized at the time of the cordocentesis as to the ultrasonographic findings, and the results were confirmed post partum; only patients who fell into the same category twice were used.

Dr. Lin asked about discordant twins. We have a couple of samples from those in the freezer, but we haven't run them yet.

Dr. Ott also asked about distinguishing between IUGR and SGA fetuses; it is true that we can't distinguish the exact cause in all those patients, but again we're trying to work on it.

There were no complications from cordocentesis in this particular series. Certainly, depending on the published series, when complications have been as high as 5% to 7% or as low as 0.5% to 1%, I think that as experience becomes greater the complication rates will go down to a point where a number of people will be able to do this procedure with safety.

I think that the issue of fetal-maternal bleeding is certainly one issue that needs to be addressed and one that needs to be looked at. We did not look at it nor were there any particular questions.

Another question was asked regarding control. The control patients were mostly patients who were being tested for diseases such as hemoglobinopathies but were found not to be affected. Anatomic defects such as limb reduction defects were felt not to be likely to affect the plasma amino acids.

Patients who had more serious internal disorders, such as hydrops, encephalocele, etc., for whom we did have a serious concern but certainly no data that there might be some impact on the circulating amino acids, were not included in this study for precisely those reasons.

As the numbers build up over time, we can probably begin to subcategorize patients by the different areas, but at this point the quickest thing to do was merely to categorize patients as easily as possible.

Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women

Abbey B. Berenson, MD,[a] Norma J. Stiglich, MD,[a] Gregg S. Wilkinson, PhD,[b] and Garland D. Anderson, MD[a]

Galveston, Texas

We investigated prevalence and risk factors associated with physical abuse among a tricultural population of 501 pregnant women who attended a public prenatal clinic. Twenty percent (98/501) reported being physically abused; 29% (28/98) stated that abuse occurred during pregnancy. More white non-Hispanic women reported previous abuse than did black or Hispanic women. Battered women more frequently were divorced or separated, were of greater parity, smoked, used alcohol, or admitted to illicit drug use than did women who were not battered. An increased risk of previous physical abuse was observed among white non-Hispanic and black women who used alcohol (odds ratios = 3.0 and 6.0) or drugs (odds ratios = 2.1 and 3.7) but not among Hispanic women. Odds ratios of 4.7 for cocaine use among white non-Hispanic women, 4.7 for marijuana use among black women, and 5.8 for tobacco use among Hispanic women were observed. This is the first study to report the effects of race on the association between physical abuse of pregnant women and sustance use. (AM J OBSTET GYNECOL 1991;164:1491-9.)

Key words: Battering, physical abuse, spouse abuse, drug use, alcohol use, tobacco use

Physical abuse has been reported to occur at least once in 28% of all United States marriages with 3.8% of all couples admitting to more violent acts than pushing, slapping, kicking, or throwing objects.[1] Most reports on abuse are derived from women in shelters, crisis centers, or emergency rooms. Few studies have addressed the prevalence of violence in a pregnant population, even though pregnancy has been suggested as a risk factor with violence either beginning or increasing during this period. Hillard[2] noted a history of physical abuse in 81 of 742 obstetric patients. Helton et al.[3] interviewed 290 women in both public and private prenatal clinics and noted a 23% prevalence with 8% reporting abuse in the current pregnancy.

Risk factors other than pregnancy reported to be associated with abuse have included alcohol or drug dependence in the male partner, violence in the family of origin of either partner, low socioeconomic status, and unemployment. Few have investigated the victim's use of illegal drugs. Kantor and Straus[4] examined marijuana use in 2033 women and noted that severely assaulted women had a usage rate six times higher in the year preceding their emergency room visit than did nonvictims but concluded that drug use among wives was not significant as a risk factor for physical abuse. In a smaller study of 49 battered women, Bergman et al.[5] noted that 16% had a history of intravenous use of psychostimulants or heroin, as compared with 2% of nonvictims, but did not further classify the drugs by type. Recently, Amaro et al.[6] reported that victims of abuse during pregnancy were more likely to use marijuana, cocaine, and alcohol than were nonvictims. However, the effects of race on the relationship between drug or alcohol use and violence during pregnancy were controlled for rather than investigated in their analysis.

The purpose of this study was to measure the prevalence of battering in a large tricultural, public, prenatal clinic population and to determine risk factors within each race–ethnic group associated with physical abuse, including the victim's use of alcohol and illegal drugs. The type of drugs used also was investigated.

Material and methods

All patients ≥18 years old who attended the university's low-risk obstetric clinic between May 8, 1989, and Feb. 5, 1990, were interviewed by their clinician for a history of physical abuse at their second visit. Eighty percent were interviewed by a physician's assistant or nurse practitioner, 15% by a resident, and 5% by a medical student. A modified version of Helton's ques-

tionnaire in Spanish and English was used, with permission, to ensure uniformity in questioning.[3] Thirty-one patients who presented during this period were not surveyed because of unavailability of a translator (one patient), refusal (one patient), or an oversight by their clinician (29 patients). After confidentiality was emphasized, 501 adults were asked privately, "Has anyone hit, slapped, kicked, or otherwise physically hurt you?" Positive responders were questioned on their relationship to the attacker, the last date of occurrence, and the body site injured at that time. Women were asked whether medical care had been sought and if battering had occurred or increased during the current pregnancy. Practical information on legal rights and community resources was disseminated to all patients. An on-site social worker counseled those with a history of physical abuse.

Women were also queried as to their use of tobacco and alcohol since becoming pregnant and whether they had used illegal drugs at any time during the last 12 months. Sociodemographic data were obtained by reviewing each patient's hospital records with institutional review board approval. Thirty-three percent of charts were reviewed a second time to assure accuracy of data entry.

The χ^2 test of independence was used to determine whether statistically significant differences were present between physical abuse and demographic characteristics. The Student *t* test was used to determine whether significant differences existed between continuous variables such as age and the presence of abuse.

After measuring the prevalence of physical abuse, we calculated the odds ratio of physical abuse relative to nonabuse by race, language spoken, marital status, employment, and use of substances including tobacco, alcohol, and illicit drugs. The prevalence odds ratio estimates the risk ratio and provides a measure of the strength of the association between the risk factors being examined and the frequency of physical abuse.[7] We also calculated 95% confidence limits on the basis of a maximum likelihood procedure that was first described by Cornfield[8] and later refined by Gart.[9]

Stratified analyses were conducted to determine the effect of race–ethnic background on the risk of physical abuse by use of tobacco, alcohol, or drugs. Asian patients were not included in the analysis by race because an inadequate number were available for comparison. Both unadjusted and age-adjusted odds ratios were calculated. A stratified maximum likelihood procedure was used to adjust for age differences.[10] The likelihood ratio test for heterogeneity was applied to the stratum-specific results to ensure the applicability of the maximum likelihood approach to age adjustment.[11] Ninety-five percent confidence limits around the adjusted odds ratios are reported.

Results

Five hundred one patients were interviewed. The population consisted of 47.5% (238/501) white non-Hispanic, 28.1% (141/501) black, 24.0% (120/501) Hispanic, and 0.4% (2/501) Asian women. Patients ranged in age from 18 to 43 with a mean (±SD) of 23.5 ± 4.5 years. Ninety-two percent (459/501) were surveyed in English and 8% (42/501) in Spanish. The 31 patients not surveyed did not differ significantly from the study population by race, age, gravidity, parity, or gestational age.

Twenty percent (98/501) of the women questioned reported having been battered (95% confidence limits = 16.1, 23.0). Twenty-nine percent (28/98) of the victims stated that abuse had occurred in the current pregnancy with six noting an increase in violence during pregnancy. Nineteen of the 98 battered women had sought medical attention.

The face was the most frequent site injured and extremities the second most common. Seven of the fourteen women who reported being struck in the abdomen were pregnant when hit. Ninety-two percent (88/96) of the women reported a single perpetrator. This was her boyfriend or spouse in 83% (73/88) of the cases. Eleven patients identified a parent as the perpetrator, two had been struck by a brother, one by a brother-in-law, and one by a non–family member. Eight patients identified more than one abuser, two of whom had been hit by a parent and a boyfriend, four by two parents or guardians, one by her exspouse and current boyfriend, and one by her boyfriend and her sister.

In patients who admitted being abused, mean gravidity and mean parity were significantly higher than in those who had not been abused ($p \leq 0.001$, $p \leq 0.001$; Table I). Battered women had more living children than nonabused women ($p \leq 0.001$). No significant differences were noted in maternal age or gestational age between women with and without a history of battering.

The prevalence of reported physical abuse was 3.5 times higher among white non-Hispanic women than it was among Hispanic women (95% confidence limits = 1.8, 6.8) and 1.6 times higher among white non-Hispanic than among black women (95% confidence limits = 1.0, 2.7). Similarly, women with a history of physical abuse were more likely to converse in English than in Spanish ($p = 0.006$).

Battered white non-Hispanic women were twice as likely and battered black women were 15 times as likely as nonbattered women to be divorced or separated when compared with women who reported a negative history of physical abuse (Table II). Married Hispanic women, on the other hand, were more likely than unmarried women to report physical abuse.

When employment status was considered, black women who had been battered were twice as likely to be unemployed than were black women who had not been battered (Table III). An association was observed between battering and status as a student among Hispanic women; however, this finding was based on only one observed case.

Table IV shows associations between physical abuse and substance use by race–ethnic group for women who reported having been battered compared with those who did not report having been battered. Abused white non-Hispanic women had 2.1 times the risk for using drugs when compared with women who had not been abused. Black women who had been battered, however, were 3.7 times as likely to have used drugs than were black women who had not been battered. None of the Hispanic patients who had been physically abused admitted to using drugs.

Age-adjusted relative risk estimates for alcohol use were elevated among white non-Hispanics (odds ratio = 3.0) and blacks (odds ratio = 6.0) but not among Hispanics (odds ratio = 1.0). The relative risk for tobacco use was elevated among all three race–ethnic groups with abused Hispanic women having 5.8 times the risk of non-abused Hispanic women followed by black and white non-Hispanic women, respectively. We also calculated crude odds ratios and pooled odds ratios that we adjusted (using maximum likelihood estimation) for the effect of race on the relationship between physical abuse and substance use. Because the race–ethnic group specific odds ratios are so different, the crude estimates are probably of less interest in this setting.

Table V shows the relationships between the type of substance used among abused and nonabused women by race–ethnic group. The relative risk of cocaine use was 4.7 for white non-Hispanic women who had been physically abused when compared with those who had not been abused. Abused and nonabused black women did not differ in their use of cocaine. The relative risk for marijuana use among abused black women, however, was 4.7 whereas the risk for marijuana use among white non-Hispanic women was 2.7. No black woman who had been battered reported using both marijuana and cocaine, but the relative risk for using both of these drugs was 2.4 among battered white non-Hispanic women.

Comment

Pregnancy has been cited as a risk factor for the initiation or escalation of physical abuse. Reasons hypothesized for abuse during pregnancy include violence directed toward the fetus, sexual frustration, stress of family transition, biochemical changes, and defenselessness of the pregnant woman.[12] More than one fourth of our patients with a history of abuse reported violence in the current pregnancy with an escalation in battering noted by six women. This study, however, most likely underestimates the number of women who are abused in pregnancy because interviews were conducted at the second prenatal visit. Since the violence cycle includes a remorseful phase with promises by the man that abuse will not be repeated, women interviewed during this phase may erroneously report that abuse has ceased. Five women, who had been struck within the last year, stated that they were not currently being abused and had not been hit in the current pregnancy, although they were still involved with abusive partners. If the interview had been conducted later in gestation, a higher prevalence of abuse during pregnancy may have been detected. However, a later survey would not have detected battered women who aborted or had a preterm delivery. The most effective screening program would include more than one interview in pregnancy.

Table I. Demographic characteristics of battered pregnant women compared with pregnant women who were not battered

	Battered	*Not battered*	*p Value*
Age (yr)	24.1 ± 4.8	23.3 ± 4.4	NS
Gravidity	3.1 ± 1.2	2.5 ± 1.6	≤0.001
Parity	1.5 ± 1.1	1.0 ± 1.2	≤0.001
Living children	1.5 ± 1.1	1.0 ± 1.2	≤0.001
Gestational age at interview (wk)	22.0 ± 9.0	22.5 ± 9.6	NS

Data are presented as mean ± SD.

We found that white non-Hispanic women were more likely to report previous battering than were blacks or Hispanics. In contrast, Helton et al.[3] found no racial differences in reported abuse. In our study Hispanic women also admitted using alcohol and drugs less frequently than did white non-Hispanic and black women. This analysis was dependent on self-reporting; therefore bias could be present if Hispanics were less likely to discuss these events openly with their clinicians. Recall bias of an event as traumatic as physical abuse is unlikely to be dependent on racial or ethnic status. Because the study population comprised pregnant women only, pregnancy itself would not contribute to recall bias since both abused and nonabused women were pregnant at the time of interview.

Although the face was the most common site hit both before and during pregnancy, the abdomen was hit almost twice as frequently in pregnant women as compared with those who were not pregnant when battered (27% vs 14%). This may represent prenatal child abuse and may result in an increased risk of an adverse outcome. Morey et al.[13] described an infant with an intraventricular hemorrhage and extensive bruises born to

a mother who was struck in the abdomen 1 week before delivery. Bullock and McFarlane[14] noted a significant correlation between battering and low birth weight in a survey of 589 adults. Further study is required to determine if physical abuse in pregnancy is associated with an adverse perinatal outcome.

Risk factors previously reported to be associated with physical abuse, in general, include being divorced or separated, being unemployed, and alcohol or drug use by either partner. Hillard[2] reported that abused pregnant women are more likely to be divorced or separated than are women who do not have a history of abuse. Appleton[15] reported that women battered multiple times were three times more likely to have been divorced than were controls. We observed that the association between physical abuse and marital status may be modified by race. Battered white non-Hispanic and black women were more often divorced or separated when compared with nonabused women of the same race. In fact, all categories of unmarried black women were at greater risk for a history of physical abuse than were married black women. Abused Hispanic women, in contrast, were more likely to be married than were those with a negative history. These findings suggest that a victim's response to an abusive situation is likely to be influenced by her culture, and in particular, Hispanic women may be more reluctant to leave an abusive partner than are white non-Hispanic or black women.

The protective role of employment outside the home is questionable. Appleton[15] did not note a difference in employment outside the home between abused and nonabused women. Gelles[16] observed that employment

could determine whether a woman sought outside assistance in an abusive situation and noted that wives who do not seek intervention are more likely to be unemployed. We observed that the association between an abuse history and unemployment varied with race with an increased risk of unemployment among battered black women but not white non-Hispanic and Hispanic women.

Our findings of an increased risk of abuse associated with the use of alcohol is consistent with findings reported by other investigators. Bergman et al.[17] reported that 51% of abused women seen in an emergency room and 88% of their assailants were heavy consumers of alcohol. Kantor and Straus[4] noted that alcohol use by either partner was a significant risk factor for abuse, and Eberle[18] found a strong correlation between alcohol use by the victim and physical abuse. Both Coleman et al.[19] and Telch and Lindquist[20] reported significantly more drinking problems in both the husband and wife of violent couples as compared with nonviolent couples. Hillard[2] detected that victims were more likely to report alcohol use than were nonbattered women. Our study of a pregnant population confirms that victims more frequently report alcohol use than do nonvictims.

The role of illicit drug use by the battered female has not been well documented. Coleman et al.[19] noted frequent legal drug use in battered wives. In a study of marijuana use in battered women, Kantor and Straus[4] noted a sixfold increase among victims of severe violence compared with nonvictims. Amaro et al.[6] observed that women hit during pregnancy were 2.7 times more likely to be heavy users of illicit drugs than were nonvictims. Appleton,[15] however, detected illicit drug use other than marijuana in only one subject out of 30 acutely battered women.

This is the first study of which we are aware that has detected differences in the relationship between race, substance abuse, and a history of battering among pregnant women from the three races–ethnic groups: white non-Hispanic, black, and Hispanic. We observed that pregnant women who had been battered reported using illegal drugs more often than women who did not report a history of physical abuse (adjusted odds ratio = 2.9, 95% confidence limits = 1.2, 4.6) and we further noted an increased risk of cocaine, as well as marijuana use, when analyzed by race. The risk of cocaine use was highest among white non-Hispanics as compared with blacks and Hispanics, while marijuana was the most common drug used by battered black women. In addition, white non-Hispanic women more frequently reported using both substances than did blacks or Hispanics.

Limited data are available regarding whether drug use represents self-medication by a depressed, battered woman or whether the environment of a substance abuser later leads to physical abuse. Dembo et al.[21] observed that battered children have lower self-esteem, less confidence, and more mistrust of others and theorized that victims use drugs as an escape from pain. One may speculate that victims of abuse attempt to cope with their situations through the use of drugs, alcohol, or tobacco and may use illegal substances as mood elevators or tranquilizers. Alternatively, the environment of a substance abuser, with its potential for violence, may increase the possibility that battering will be experienced. Drug addiction may further hinder the victim by increasing the difficulty of leaving an abusive partner, especially if he supplies the drug or provides the finances for its purchase. Further study in this area with confirmatory urine testing for drugs is warranted.

In conclusion, a prevalence of 20% for previous physical abuse was reported in a pregnant population with almost one third of the battered subjects reporting abuse during the current pregnancy. Differences between battered and nonbattered pregnant women included race, marital status, employment status, parity, and use of tobacco, alcohol, and drugs with battered women of each race demonstrating a different profile.

Clinicians who provide prenatal care should be aware of the risk factors that place pregnant women at an increased risk for a history of physical abuse. Knowledge of risk factors particular to the patients' race or ethnic group may help identify those who are at risk of physical abuse. However, no stereotype of a battered pregnant woman is available. Therefore all pregnant women should be screened by direct questioning to allow counseling, referral, or even legal action to be invoked before serious injury to the mother or the fetus is experienced.

We thank Julie Baker, Joan Self, Glenda Saenz, and the clinical staff of the low-risk clinic for their assistance and Johnebelle Hankins for manuscript preparation.

Editors' note: This manuscript was revised after these discussions were presented.

Discussion

Dr. Richard P. Perkins, Omaha, Nebraska. The authors have presented the results of a substantial interview survey of pregnant women of varied ethnic backgrounds concerning the prevalence of physical abuse before and during pregnancy. The data are well collected and analyzed. They point out that traditional risk factors such as alcohol use in the male, low socioeconomic status, and unemployment were well represented in the study population. These findings are not news. What is stressed is the finding of an association with drug use among the victims.

In this population all patients were at least 18 years old and were "low-risk" obstetric clients (however one can define that in a clinic population). The ethnic groups were of sufficient numbers for meaningful analysis. There was a 20% history of abuse of some sort in the past, and almost 20% of these sought medical attention (or protection) for these incidents. In some cases the abusive behavior increased during pregnancy. In most cases abuse was by one person, usually the mate.

Anglo women reported a greater frequency than black or Hispanic women. English-speaking Hispanics, presumably reflecting Anglo acculturation, reported a higher incidence than others in that ethnic subset. Battering was seen much more often among black women who were unemployed than among black workers.

Drug use, including alcohol, tobacco, and marijuana, was usually increased in Anglos and blacks who reported abuse. Hispanic smokers showed a greatly increased risk. More battered Anglo and black women were divorced than married. Unwed and/or unemployed blacks were disadvantaged in partner treatment, yet the reverse was true for unwed Hispanics. It is very possible that Hispanic women are far less likely to admit to this treatment than others, because in my experience with Hispanic clients there was a lot of this behavior.

The findings are compatible with results of prior studies cited by the authors, yet some fundamental questions remain unanswered. *The single most important of these is, which comes first, the drug use or the battering?* Is the battering reflective of a general pattern of self-abuse, of which drug use is yet another example? Or are these women using drugs to escape the horrors of their lives? Or are they just in a consistent pattern of making the wrong choices for themselves in all areas of their lives? Does drug use make one more prone to battering through the effects of the drug on behavior? If the latter were so, one should not see it in marijuana smokers, I should think, as they are often mellow to a fault. Cocaine abuse, on the other hand, frequently is associated with aggressive behavioral traits.

Alcohol use was especially prevalent among partners of alcohol-abusing women. This is representative of the axiomatic state of life among drug users: It is as likely that only one of a family uses drugs as it would be to have only one cockroach. Do drunks really like each other, as we would be asked to believe sometimes? Most would say no and that they remind them too much of themselves.

The data raise other questions. Do unemployed women experience abuse simply because they are more available to their equally unemployed and frustrated partners?

Of interest, the abused women in this study were of the same average age as controls but had more children. Do children raise the level of tension in a stressed home environment? Undoubtedly they do.

Finally, it should be noted that the abusive partner may be using the only effective decompression mechanism of which he (or sometimes she) is capable. Tensions build and resources for alleviating them through reason, discussion, diversion, or other intellectual avenues fail. Some humans lose what limited articulateness they normally possess during such emotional states. Perhaps we can approach this problem in the future of man through a concerted effort toward teaching our children the values of resolving conflicts peacefully and through discussion instead of by a variety of physical exercises and brandishing of arms. Strength of will must be as attractive as strength of body, especially when the potential for equality of the sexes is at issue. Of course, eminent success in this venture would leave us without any soldiers. Opinions as to the significance of this surely would vary.

I reiterate my greatest curiosity. Of drugs and battering, which is the initial abnormal event?

Dr. Mary Jean Cannon, Chicago, Illinois. Dr. Berenson and her co-workers have undertaken a study to determine the prevalence of physical abuse in a multiracial pregnant population, specifically to identify risk factors for this behavior within racial groups. Their purpose was valid for a number of reasons: First, there is a paucity of information, especially in the last decade, regarding physical abuse of pregnant women in general. Second, physical abuse in pregnancy is of concern to all obstetricians, particularly in its less recognizable forms. The identification of risk factors to alert physicians to this problem could prevent unnecessary fetal and maternal harm. Last, since risk factors cited in this article such as drug, alcohol, and tobacco use are already routinely screened for in pregnant populations, new information concerning these factors could be of immediate practical significance. The goals of this study were accomplished by the confirmation of many interesting points, four of which I would like to comment on: (1) The authors reported a 20% prevalence of battering among women in their low-risk prenatal population. This high figure appears to be consistent with other reports of similar populations in the literature[1] and should serve to raise our consciousness about this probably grossly underreported problem. Patients in this study, however, were from a clinic setting and not from private offices. Can we extrapolate these results to society in general or do socioeconomic levels influence prevalence? (2) The investigators also showed an increased frequency of battering during pregnancy in 6% of cases and a decreased frequency of battering during pregnancy in 5% of cases. This appears to indicate no overall escalation of abuse during pregnancy as other studies claim. Furthermore, since no information was given regarding the onset of first battering, no conclusions can be drawn about whether pregnancy itself is a risk factor for the initiation of abuse. (3) Next, the manuscript stated that twice as many Anglo women as black or Hispanic women reported being physically abused. Does this represent greater reluctance on the part of black and Hispanic women to disclose this private and painful information for cultural reasons, is it simply a language miscommunication, or is it truly a difference in prevalence? Discussion should speculate about this finding. (4) Last, abused Hispanic women were more likely to be married than were nonabused Hispanic women. This is a reversal of the situation for Anglo and black women. It is difficult to interpret marital status as a risk factor, at least in Hispanics. Lower divorce rates are probably accounted for by the fact that the Hispanic population is largely Catholic.

The design of this study allowed for the collection of a large amount of data and the authors should be complimented on its detailed statistical analysis. I am uncertain, however, as to why patients under the age of 18 were excluded from the study sample and why only a low-risk population was queried. I also question the timing of patient interviews and why, as the authors commented, they chose not to delay questioning until the third trimester when a higher prevalence of abuse may have been detected. The addition of a table of demographic information including variables such as parity and socioeconomic status may serve to clarify the study population's characteristics.

Merit in this article lies in its ability to heighten awareness among health care providers of the very real and not so rare problem of physical abuse of the pregnant woman. Practically speaking, however, it is impossible, on the basis of the risk factors analyzed in this manuscript, to formulate the profile of a typical battered woman. The investigators have clearly demonstrated significant variations among the three racial groups studied. Fortunately, the habits of drug, alcohol, and tobacco use, as well as the history of an unstable marital relationship, in pregnant women usually alert clinicians to the need for closer pregnancy surveillance. Hopefully, this would lead to the discovery of an abuse problem if one existed. However, this is not enough. The screening of pregnant women must include some active assessment of their physical safety.

I would encourage these investigators to continue their work in this area, perhaps next sharing with us information regarding pregnancy outcomes in this series. It still remains to be seen whether identifying risk factors will actually prevent abuse.

Finally, I would like to draw attention to an excellent program funded by the March of Dimes Birth Defects Foundation designed to educate health care providers and the general public about battering during pregnancy, which was successful in the Houston area. Educational materials, as well as protocols of care for battered women, are available from this organization.

REFERENCE

1. McFarland J. Battering during pregnancy: tip of an iceberg revealed. Women Health 1989;15:69-84.

Dr. Pedro A. Poma, Melrose Park, Illinois. I just want to underscore that spouse abuse may occur at any socioeconomic and educational levels. It occurs in most ethnic groups.

I also want to tell the authors that probably the word *Anglo* does not represent the ethnic background of the group they want to identify. In this country only a small percent have an Anglo background (i.e., people from England). A more appropriate name for such a group would be *non-Hispanic.*

Dr. Herbert F. Sandmire, Green Bay, Wisconsin. I would like to ask the authors who were the perpetrators—the other 20% who were not the spouse or boyfriend?

Dr. Daniel A. Rightmire, Springfield, Illinois. I have a number of comments. First, statistically speaking, gravidity, parity, and number of children are not continuous variables and should not be summarized by parametric statistics.

Second, it should be noted that a number of the variables are highly correlated and are not independent.

Another problem is that the study population was self-identified. Is there some other, more objective way of identifying physically abused persons? For example, creatine phosphokinase values might serve as an objective laboratory marker of physical abuse.

It is difficult to find a control or reference population or to quantitate the amount or frequency of violence in a person's life. Does the percentage of male spouses abused by pregnant women vary by race?

Dr. Washington C. Hill, Nashville, Tennessee. First, I congratulate the authors, particularly in viewing a subject and studying a subject that many of us are very reluctant to talk about.

I have two questions. The first is, since you took the time to look at this problem, I would like you to speculate on what you think you would find when you look at your private patients instead of your clinic patients. Also, what do you want to give as a take-home message to those of us who are seeing patients in our private practice?

Dr. Jacques F. Roux, Jackson, Wyoming. In Jackson, Wyoming, about 29% of women are possibly abused before pregnancy. They seem to accept abuse as a matter of fact. I wonder if this attitude could be related to their childhood experiences. For instance, a family member could have abused them sexually at an early age. This kind of data may reinforce the conclusions of this presentation.

President Malinak. I would like to ask Dr. Berenson a few questions. First, was the same question asked to those patients in your hospital who presented with no prenatal care? In other words, do you know the incidence of abuse in women who did not have prenatal care?

Second, were there differences in low-birth-weight infants in the abused versus nonabused groups of women?

Dr. Berenson (Closing). I would like to thank the discussants for their very kind remarks.

First, to answer Dr. Perkins' question, which comes first, drug abuse or battering? I don't think we have a definitive answer to that question, but I can speculate that women who use drugs are at higher risk of being abused on the basis of studies that demonstrated that children who were abused seemed to be at higher risk of using drugs. Other people who have done work in this field speculate that drug use may be an escape from both psychologic and physical pain as Dr. Perkins suggested.

It was also asked why we used patients over the age of 18, low-risk patients, and why they were screened at their second prenatal visit. You would have to understand a little bit about the University of Texas Medical Branch system, where I am from, to see why we set it up this way. This was a pilot screening program to detect physical abuse in our pregnant population, and the first clinic we set it up in was our low-risk prenatal clinic.

We have clinics in about 10 different counties, and we did not attempt to start screening every place at once. The second prenatal visit was chosen even though we realized it would miss some patients who were abused later in pregnancy because this allowed all women to be screened at least once. If we had chosen another time, for example, at 36 weeks' gestation, those who had a preterm delivery or an abortion might have been missed.

Can these results be applied to all women in our society? No, I don't think you can say that on the basis of this article. You have to keep in mind our population. We are screening women of childbearing age who are in a low socioeconomic status and who presented for prenatal care. We have not yet looked at some of the other groups that have been mentioned.

Is pregnancy itself a risk factor for abuse? We did find several patients who reported a decrease in abuse or an increase in abuse in pregnancy, but the numbers are too small to state that pregnancy was or was not a risk factor for abuse.

An important question was raised on whether Hispanic women underreport a history of battering. On the basis of anecdotal reports from our hospital, Hispanic patients are more reluctant to disclose physical abuse. More husbands of Hispanic women accompany their wives to the prenatal clinic and sometimes have to be asked to leave the room so that the survey can be conducted in private.

We are beginning to look at the outcome of the pregnancy in the first half of these patients that were screened, and to date we've found no difference in gestational age at the time of delivery or in Apgar scores. We plan to investigate this further.

I think the point is well taken that physical abuse occurs in families of all socioeconomic levels. We will probably never be able to determine the prevalence in a private population at our institution because we only have 10% of private patients.

I think the take-home message for those that work in clinics or private practice is that we need to screen our obstetric patients for a history of physical abuse. It's a very common event. It occurs in pregnancy, and we don't know whether the fetus is being placed at risk. We certainly will never know which patients are at risk if we don't ask.

Many of the women were very relieved to have someone just ask if something was going on. The reason we began screening was not primarily for research but to improve prenatal care and to educate women through counseling by a social worker.

It was pointed out that the variables are highly correlated, and I think that is true. We did attempt to adjust for age because we found that our drug-using population was older than our non-drug-using population, but many of these variables are highly correlated.

We did not investigate the men. We did not ask about their drug abuse or alcohol problems, and we do not know their races.

I hope this answers all of the questions.

The natural history of HELLP syndrome: Patterns of disease progression and regression

James N. Martin, Jr., MD, Pamela G. Blake, MSN, Kenneth G. Perry, Jr., MD,
James F. McCaul, MD, L. Wayne Hess, MD, and Rick W. Martin, MD
Jackson, Mississippi

Despite much recent interest in HELLP syndrome (hemolysis, elevated liver enzymes, and low platelet count), there is little published information about the natural history of this unique form of severe preeclampsia-eclampsia. The time course and pattern of laboratory abnormalities for 158 patients with HELLP syndrome managed in a single tertiary referral center between 1980 and 1989 were studied retrospectively. Despite considerable patient variation, most gravid women with HELLP syndrome had decreasing platelet counts until 24 to 48 hours after delivery. Conversely, lactate dehydrogenase concentrations usually peaked 24 to 48 hours post partum. In all patients who recovered, a platelet count $>1,000,000/mm^3$ was spontaneously achieved by the sixth postpartum day or within 72 hours of platelet nadir. An upward trend in platelet count and a downward trend in lactate dehydrogenase concentrations should be apparent in patients without complications by the fourth postpartum day. These data provide baseline information against which the course of individual patients can be compared and the infrequent, atypical case identified for interventive therapy. (AM J OBSTET GYNECOL 1991;164:1500-13.)

Key words: Severe preeclampsia-eclampsia, HELLP syndrome, natural history

HELLP syndrome (hemolysis, elevated liver enzymes, and low platelet count) is a multisystem disease form of severe preeclampsia-eclampsia that is characterized by microangiopathic hemolytic anemia, hepatic dysfunction, and thrombocytopenia and that, in most severe cases, progresses to disseminated intravascular coagulation.[1-8] Insidious in onset, obtuse to easy clinical recognition, and often misinterpreted as a nonobstetric disorder, HELLP syndrome affects an estimated 4% to 12% of patients with severe preeclampsia.[9-13] Recognition of its presence usually is triggered by clinical signs and symptoms of hepatic involvement such as epigastric pain, hepatic or right upper-quadrant tenderness, nausea, and malaise. Because HELLP syndrome often is not attended by the usual signs and symptoms of its parent disease preeclampsia (severe hypertension, proteinuria), in its earlier, milder form it can be missed unless appropriate laboratory assessment is performed by an alert clinician. Thus the HELLP process is often advanced before an accurate diagnosis is made, rendering it difficult to identify patients for study early in the course of the disorder.

Presently there are only two large published studies of patients with HELLP syndrome.[4,9] In spite of these data, there is a paucity of information regarding the natural history of this unique pregnancy-associated condition, especially in relation to patterns of laboratory parameters observed during the peripartal course.

The purpose of this report is to communicate the findings from a large population of patients with HELLP syndrome specifically related to the natural history of this disorder as reflected by the pattern and time course of laboratory abnormalities.

Patients and methods

A computer search of the medical records of all obstetric patients delivered at the University of Mississippi Medical Center between Jan. 1, 1980, and March 31, 1989, was undertaken to identify all patients with HELLP syndrome. Inclusion criteria were as follows: (1) thrombocytopenia defined as a peripartal platelet concentration $\leq 100,000/mm^3$ associated with a normal platelet count documented prenatally or during the postpartum period; (2) evidence of hepatic dysfunction to include an increase (mean ± 3 SD above third-trimester normal values) in aspartate aminotransferase (≥ 48 IU/L), alanine aminotransferase (≥ 24 IU/L), or lactate dehydrogenase (≥ 164 IU/L); (3) evidence of intravascular hemolysis to include a decreas-

ing hematocrit concurrent with worsening thrombocytopenia, an increase in lactate dehydrogenase, and/or evidence of bleeding involving gums, intravenous sites, or hematuria; (4) no evidence of another disorder primarily causative of the laboratory and clinical findings.

During the 111-month period, 158 pregnancies met inclusion criteria for HELLP syndrome. All pregnancies were subclassified into one of two classes of HELLP syndrome on the basis of only the lowest platelet count recorded at any time during the patient's peripartal course. In patients with class 1 HELLP syndrome platelet counts fell ≤50,000/mm^3; class 2 HELLP syndrome includes patients whose platelet nadir occurred in the range of >50,000/mm^3 to ≤100,000/mm^3.

The hospital chart for each affected pregnancy in this study was reviewed extensively, and pertinent data were entered into a computerized relational data base before statistical analysis. The two classes of HELLP syndrome (classes 1 and 2) considered in this portion of a larger ongoing group of investigations of the entire study population were compared by χ^2 analysis for categoric data and analysis of variance for continuous data; a difference was considered significant at $p < 0.05$.

Results

Inclusion criteria for this investigation were satisfied by 158 gravid women including 92 primigravid (58.2%) and 66 multiparous (41.8%) women. Black patients constituted the majority (110 or 69.6%) of patients with HELLP in both class groups; additionally there were 39 white patients and 9 native American patients. Mean age (±SD) of all patients was 22.9 ± 5.5 years with a range of 14 to 42 years. The mean weight (±SD) for all patients was 161 ± 34.7 pounds and mean height (±SD) was 63.8 ± 3 inches. There were no significant differences between the class 1 and 2 HELLP patient groups.

The length of time between hospital admission and delivery ranged between 1 and 61 hours in the class 1 patient group with a mean interval (±SD) of 11.4 ± 11 hours; only 4 of 70 patients (5.7%) remained undelivered >24 hours in this group. Analysis of the data for class 2 patients revealed an admission-to-delivery time interval of 2 to 81 hours with a mean (±SD) of 15.6 ± 15.3 hours; it exceeded 24 hours in only 12 of 88 patients (13.6%).

At the time of hospital admission, only 24 of 70 pregnancies (34%) eventually determined to have class 1 HELLP syndrome had a platelet count ≤50,000/mm^3 (Fig. 1, top). Later, at delivery, 33 of 68 evaluable pregnancies (48.5%) had a fall to this platelet concentration. The highest percentage of class 1 patients with a platelet concentration ≤50,000/mm^3 (65.6%) occurred on the first postpartum day. By the sixth postpartum day only 6 (6.6%) class 1 patients remained in the ≤50,000/mm^3 range. All recovered by the eleventh postpartum day. The platelet nadir for patients in class 1 occurred on admission in 9 patients (13%), at delivery in 20 (29%), on postpartum day 1 in 21 (30%), on postpartum day 2 in 15 (21%), on postpartum day 3 in 2 patients, on postpartum day 5 in 2 patients, and on day 7 in one late postpartum patient with eclampsia (Fig. 1, bottom).

Data for pregnancies later classified as class 2 HELLP syndrome were similar to those for class 1. Only 26 of 88 pregnancies (30%), when patients were first admitted to the hospital, had a platelet count in the class 2 range of >50,000/mm^3 to 100,000/mm^3 (Fig. 2, top). At delivery 48 of 88 pregnancies (54.5%) were within the final HELLP classification range. The highest percentages of class 2 patients within a platelet concentration of >50,000/mm^3 to 100,000/mm^3 occurred on postpartum days 1 (69.2%) and 2 (70.8%). By postpartum day 6 all class 2 HELLP pregnancies exceeded a platelet concentration of ≥100,000/mm^3. The platelet nadir for patients in class 2 occurred on admission in 8 patients (9%), at delivery in 19 patients (21%), on postpartum day 1 in 32 (37%), on postpartum day 2 in 23 (26%), and on postpartum day 3 in 6 (7%) (Fig. 2, bottom). Combined data for all patients in classes 1 and 2 including all recorded platelet measurements are depicted in Fig. 3.

The rate of platelet decrease per day between hospital admission and delivery was determined in 139 of the 158 combined patients from classes 1 and 2; in 19 others (9 in class 1, 10 in class 2) a platelet nadir was achieved at hospital admission and increased (primarily as a result of platelet transfusion in 14 of the 19 patients) or remained relatively unchanged thereafter (Fig. 4). At the time of hospital admission, patients with HELLP syndrome fell into one of four ranges of platelet concentration. First, 30 of 158 patients (19%) were admitted with a normal platelet concentration (>150,000/mm^3). Between admission and delivery, in half of this group, a 40% decrease in platelet concentration within the normal range was demonstrated. In the other 15 patients a mean platelet decrease of 43% to concentrations between 100,000/mm^3 and 150,000/mm^3 (9 patients) or between 50,000/mm^3 and 100,000/mm^3 (6 patients) was demonstrated. Second, in 55 of 158 patients (35%) concentrations ranged between >100,000/mm^3 to ≤150,000/mm^3 at the time of hospital admission; in 34 patients platelet counts decreased 24% to remain within the same platelet range, in 18 (28%) they decreased to the >50,000/mm^3 to ≤100,000/mm^3 range, and platelet concentrations of 3 patients decreased 53% to <50,000/mm^3. Third, 49 patients (31%) were admitted with a platelet range be-

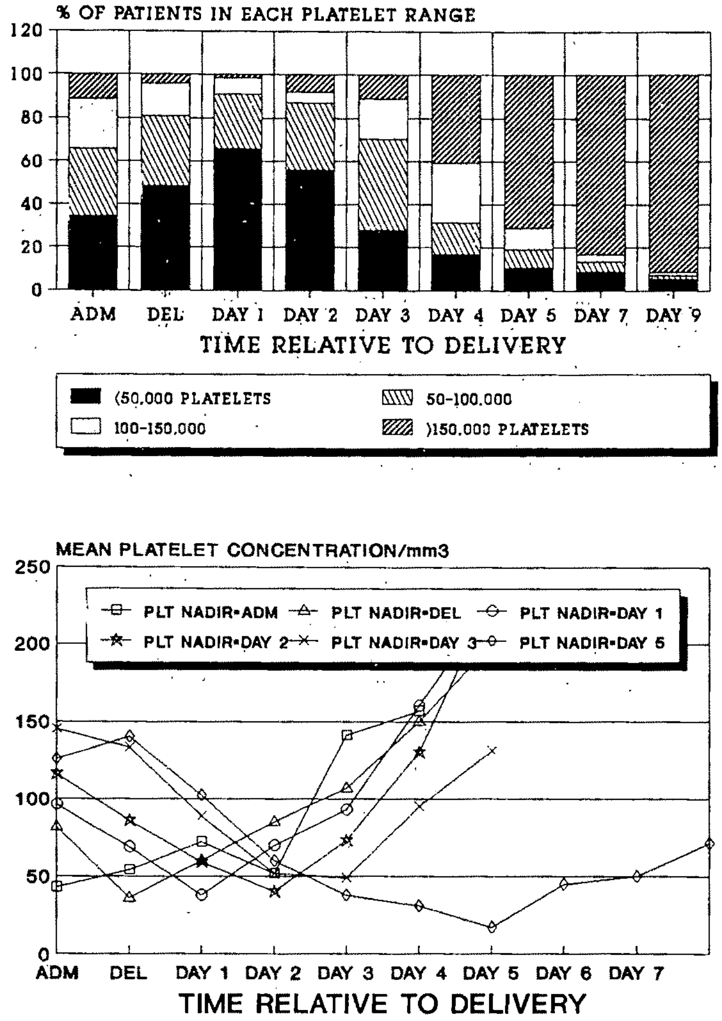

Fig. 1. Range of distribution of platelet counts at various intervals before and after delivery during clinical courses of 70 pregnancies with class 1 HELLP syndrome *(top)* and platelet means for groups of patients with platelet nadirs on different peripartal days *(bottom)*.

tween >50,000/mm^3 and ≤100,000/mm^3; in 29 concentrations remained within this range with an average 23% decrease and in 10 concentrations fell an average of 51% to <50,000/mm^3. In 10 other patients (5 were transfused) a 20% increase was demonstrated within the same range with only one value in excess of 100,000/mm^3 platelets. Finally, 24 patients (15%) with HELLP syndrome were admitted with platelet values ≤50,000/mm^3; values decreased in 13 (36%) before delivery whereas in 2 other patients they decreased 21% and then increased, along with 9 others (transfused), into the 50,000/mm^3 to 100,000/mm^3 range at the time of delivery (Fig. 4).

The percentage of patients in each of the two HELLP classes that exceeded a lactate dehydrogenase serum concentration of 600 IU/L was plotted for each day relative to time of delivery (Fig. 5). This figure was exceeded in the largest numbers of patients on postpartum day 2 for class 1 patients (64%) and on postpartum day 1 for class 2 patients (31%). Thereafter, there was a downward trend in both classes with exceptional persistent elevations or rising concentrations in the few patients in class 1 who eventually underwent plasma exchange therapy. An inverse relationship between the trends in platelet values and lactate dehydrogenase concentrations was seen in both classes of HELLP patients (Fig. 6). Serum concentrations of aspartate aminotransferase and alanine aminotransferase generally paralleled lactate dehydrogenase during the course of HELLP syndrome but at comparatively much reduced serum concentrations as illustrated in Fig. 7. Of the two tests of liver function, aspartate aminotransferase was generally higher than alanine aminotransferase during the acute phase of the disease, around delivery. At this time the largest difference between the two values was apparent. During recovery the aspartate

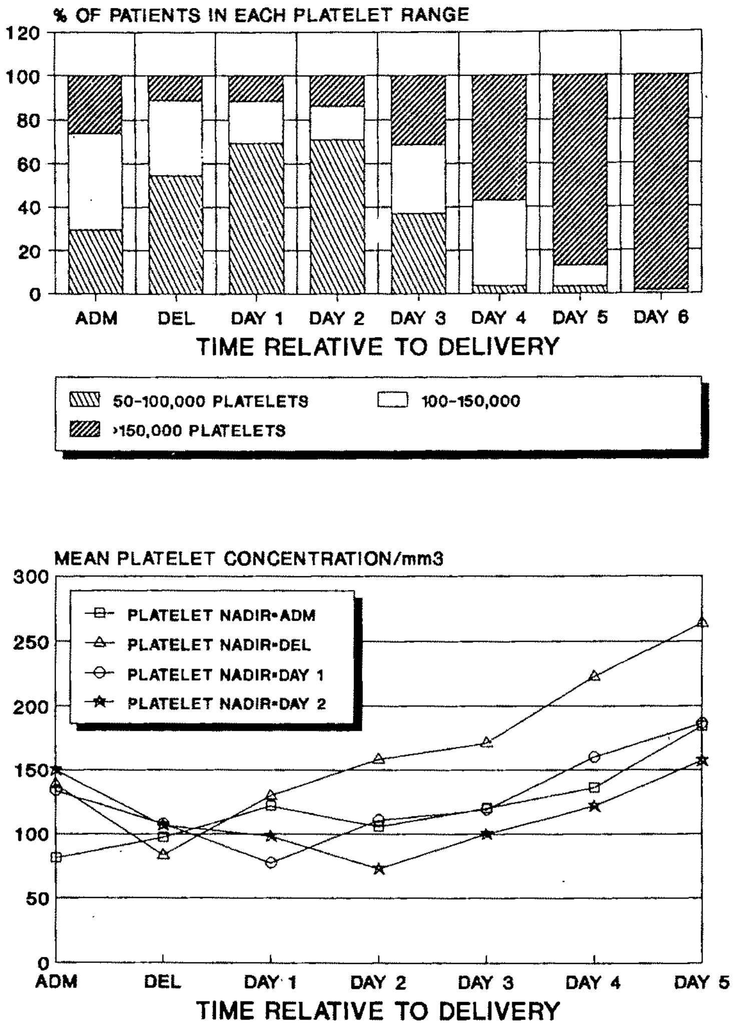

Fig. 2. Range of distribution of platelet counts at various intervals before and after delivery during clinical courses of 88 pregnancies with class 2 HELLP syndrome *(top)* and platelet means for groups of patients with platelet nadirs on various peripartal days *(bottom)*.

aminotransferase/alanine aminotransferase ratio decreased and eventually reversed or reached parity.

The relationship between mean hematocrit and platelet concentration relative to time of delivery in class 1 and 2 patients who did not receive red blood cell or platelet transfusions is shown in Fig. 8. A downward trend in hematocrit after admission and delivery generally continued until the second (class 1) or third (class 2) postpartum day.

Eleven patients in the class 1 study group underwent plasma exchange therapy. Four were treated in the immediate peripartal period (±24 hours of delivery) for unusually severe disease manifestations, including worsening severe thrombocytopenia with clinically evident bleeding, persistent clinical deterioration despite conventional transfusion therapy, and worsening neurologic status with concern for intracranial bleeding. The other 7 patients underwent exchange between the third and ninth postpartum day as described in detail recently.[14] All of the 7 patients but one had postpartum evidence of persistent or worsening severe thrombocytopenia in association with rising lactate dehydrogenase concentrations. The single exception was a patient that failed to show evidence of HELLP syndrome until the sixth postpartum day after an eclamptic seizure.

Comment

The patient population presented in this investigation represents the largest single group of patients with HELLP syndrome found in the obstetric literature. The most important finding of this study is the demonstration of the dynamics of this disease process as reflected in constantly changing laboratory parameters and the demonstration of how the patterns of disease progression and regression occur at variable time intervals in

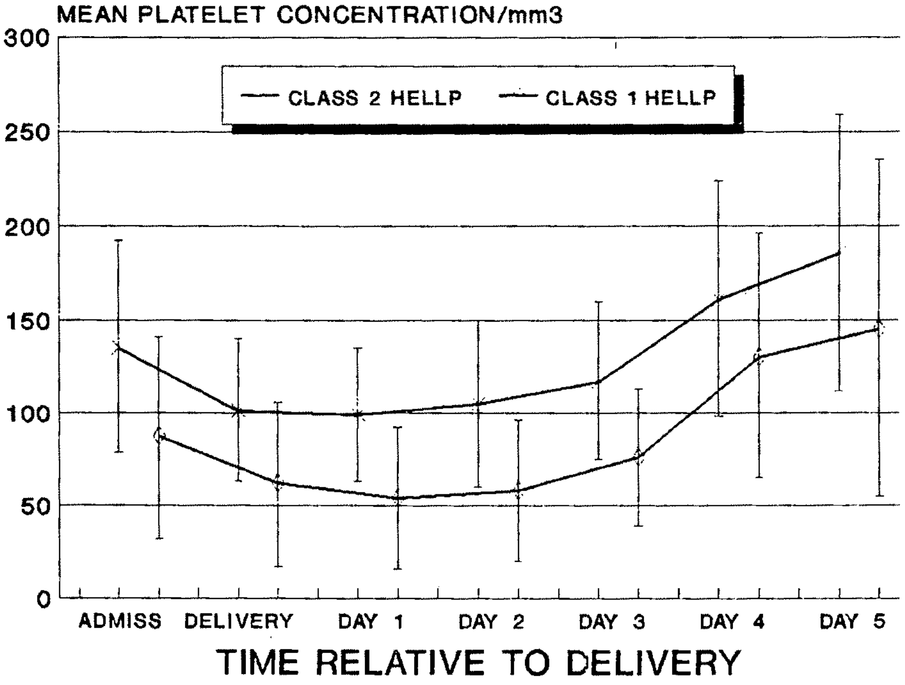

Fig. 3. Plotted platelet count means for all class 1 and class 2 HELLP pregnancies with platelet nadirs on day of hospital admission, day of delivery, or postpartum day.

HELLP syndrome. The disease appears to achieve peak intensity during the 24 to 48 hours after delivery. How rapidly a patient recovers from HELLP-complicated preeclamptic pregnancies depends on a number of factors, including when in the course of disease progression the pregnancy termination occurs. A small subset of patients appear to have such severe multisystemic disease that even discontinuation of pregnancy is in-

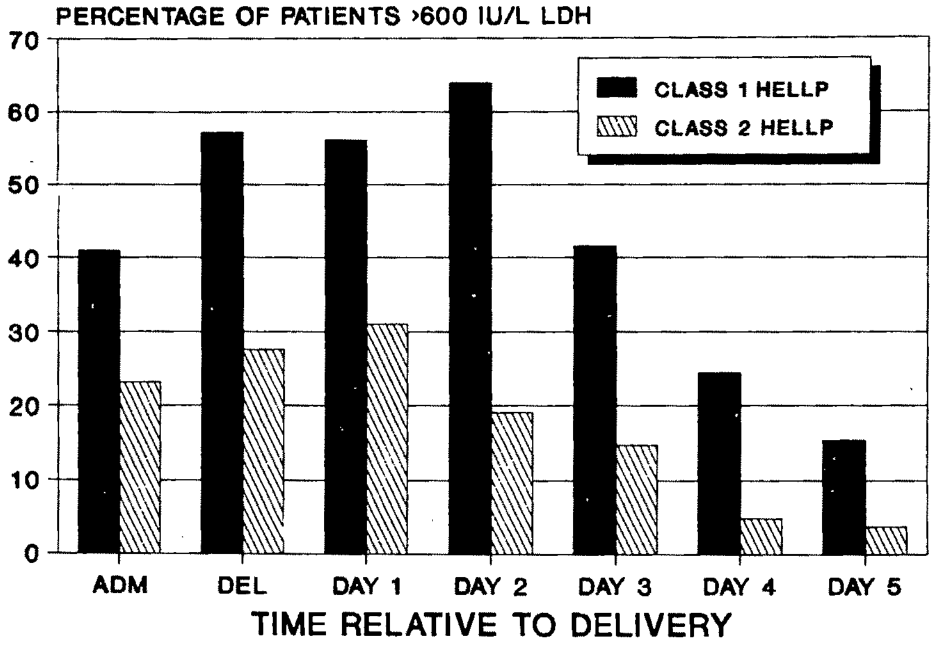

Fig. 5. Percentages of patients in class 1 and class 2 HELLP syndrome each day with lactate dehydrogenase values > 600 IU/L.

adequate to ensure timely recovery, if at all, and other treatment such as plasma exchange is necessary.[4, 15-19]

Because of the dynamic natural history of HELLP syndrome, prospective attempts at disease subclassification with prediction of eventual disease severity is a frustrating undertaking. The retrospective classification system used for the analysis of patients in the Mississippi study population has been utilized to standardize evaluation of these patients and permit comparative assessment of a number of parameters pertinent to clinical management concerns. Recently, Van Dam et al.[20] reported laboratory findings related to the development of disseminated intravascular coagulation in 18 patients with HELLP syndrome. Interestingly, the first two of their three categories of "manifest," "suspected," and "no evidence of" disseminated intravascular coagulation compare closely with the platelet counts used retrospectively to classify patients in this investigation as having class 1 or 2 HELLP syndrome.

Three other groups of investigators also have attempted to plot the course of thrombocytopenia and other laboratory parameters in the course of peripartal HELLP syndrome. Stedman et al.[21] in Birmingham evaluated 12 patients with severe preeclampsia or eclampsia and coincident HELLP syndrome during and after delivery. All patients were delivered within 24 hours of admission, and laboratory measurements were continued until test results returned to normal values. Patients in this study had a mixture of class 1 and class 2 disease with platelet nadirs between 22,000/mm³ and 55,000/mm³. The lowest observed platelet count occurred at a mean of 23 hours postpartum, a result very similar to that of this investigation. The mean maximal aspartate aminotransferase level of 694 IU/L was 17 times the upper limit of normal. There was a return of aspartate aminotransferase toward normal values within 3 to 5 days after delivery. Maximal lactate dehydrogenase levels ranged from 581 to 2380 IU/L with a mean of 1369 IU/L. In 7 of 10 patients lactate dehydrogenase values exceeded 900 IU/L.

Catanzarite[22] retrospectively reviewed the perinatal course of 79 women with HELLP syndrome whose platelet counts fell below 80,000/mm³. This investigator also found that the lowest platelet count did not predict peak values of aspartate aminotransferase or lactate dehydrogenase and that the peak alanine aminotransferase was lower than the peak aspartate aminotransferase with a mean ratio of 0.55. The degree of abnormality of platelet count, aspartate aminotransferase, and lactate dehydrogenase did not prospectively and accurately predict time to recovery. Consistent with the findings in this report, Catanzarite observed that the lowest platelet count and mean aspartate aminotransferase and lactate dehydrogenase occurred within 72 hours of delivery in almost all cases. At 5 and 7 days after delivery, platelet counts were above 100,000/mm³ in 85% and 96% of his cases, respectively. Aspartate aminotransferase values were below 70 IU/L in 85% and 96% and lactate dehydrogenase values were below 400 IU/L in 76% and 89% at 5 and 7 days, respectively.

Neiger et al.[23] prospectively followed up 20 patients with class 1 and 2 HELLP syndrome. The mean platelet nadir for the group was 50,000/mm³ and the

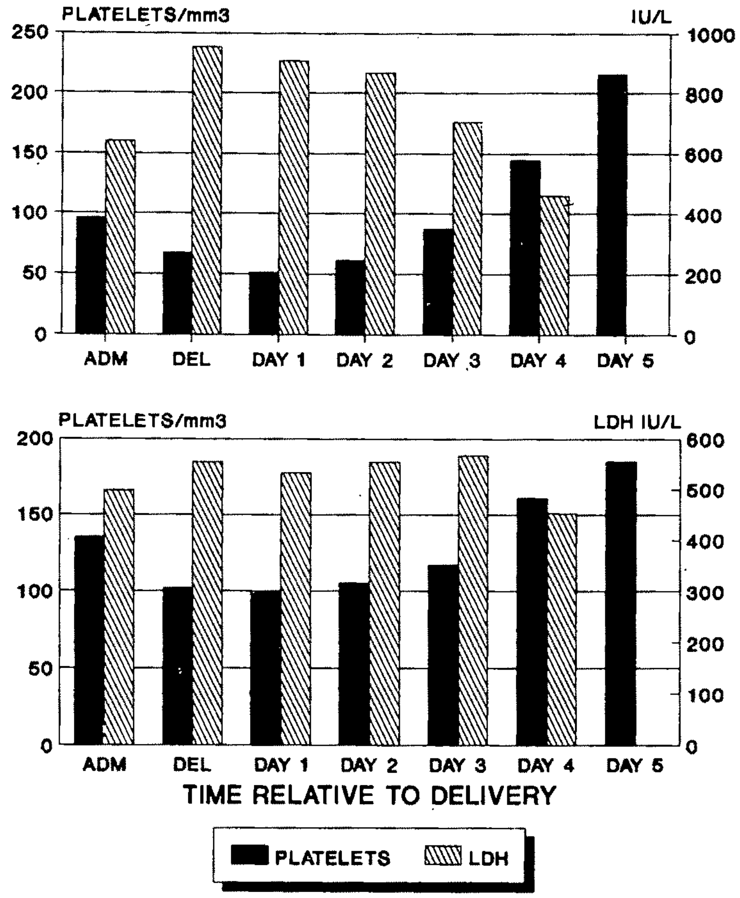

Fig. 6. Daily mean platelet counts and lactate dehydrogenase serum concentrations from admission through fifth postpartum day, plotted with *bars* for pattern comparison in class 1 *(top)* and class 2 *(bottom)*.

average time from delivery to platelet count recovery >100,00/mm^3 was 82 hours. The value was somewhat skewed because two patients required 140 and 270 hours for spontaneous platelet recovery whereas the other 18 recovered by the fifth postpartum day.

Although several investigators have attempted to define the parameters of recovery for patients with HELLP syndrome, no information to date is available regarding the rapidity with which the disease worsens. In this investigation the retrospective data suggest that at least 88% of patients with either class 1 or 2 HELLP syndrome experience worsening thrombocytopenia until and for many hours after delivery. Regardless of whether the platelet count at the time of hospital admission is in the normal range or as low as <50,000/mm^3, patients in both HELLP classes usually showed evidence of a decreasing platelet count at the average rate of approximately 40% per day. A downward trend in platelet count and an upward trend in lactate dehydrogenase and transaminase serum concentrations persists in most patients into the second postpartum day before a trend toward normalization begins. The line plots in Fig. 3 show that the platelet count should be expected to exceed the 100,000/mm^3 level no longer than 72 hours after platelet nadir (*not* delivery) occurs, unless the patient has severe, atypical disease. Stated another way, an upward trend in platelet count should be apparent by the fourth postpartum day. Despite the limitations of the retrospective nature of this investigation, it has been demonstrated that a return to normal laboratory parameters appears to be dependent largely on when laboratory nadirs occur for the various tests of dysfunction in HELLP syndrome.

It appears that patients with class 1 HELLP syndrome require a longer interval of time for complete resolution of thrombocytopenia, hemolysis, and liver dysfunction. Although all patients with class 2 HELLP had an increase in platelet counts to >100,000/mm^3 by the sixth postpartum day, a small number of patients in class 1 had persistence in the <50,000/mm^3 range for several days thereafter, until plasma exchange was undertaken. In this patient series it was not until the eleventh postpartum day that all patients in class 1

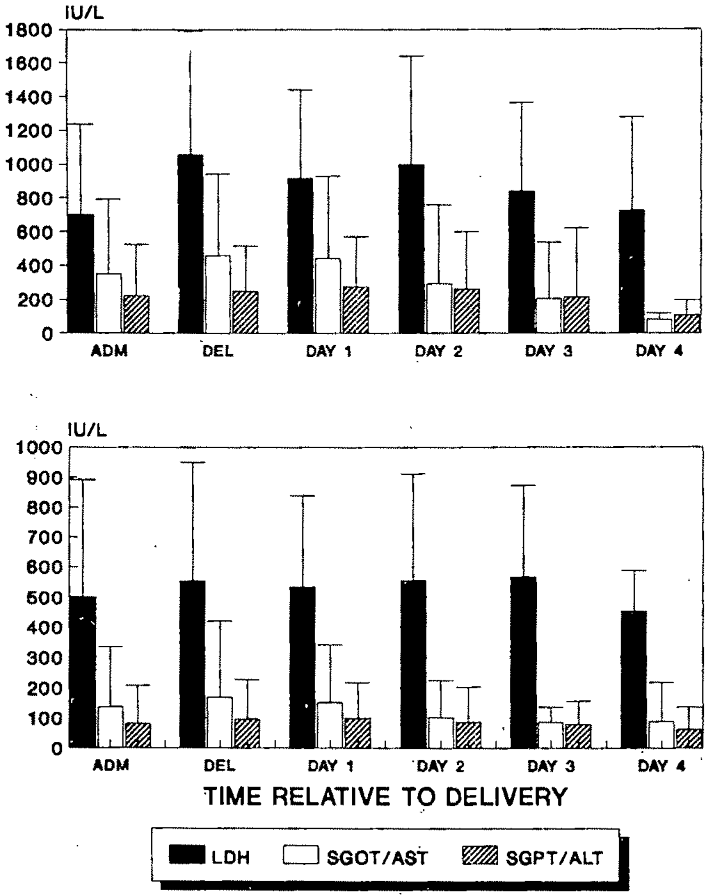

Fig. 7. Mean values of lactate dehydrogenase, aspartate aminotransferase, and alanine aminotransferase for all patients with class 1 HELLP syndrome *(top)* and class 2 HELLP syndrome *(bottom)*, plotted from hospital admission through fourth postpartum day.

had a return with assistance to a platelet concentration $>100,000/mm^3$.

The difference between class 1 and class 2 platelet normalization patterns is primarily accounted for by a small number of patients who failed to recover spontaneously and instead had persistence of severe atypical systemic disease. Seven patients in this series underwent single or repetitive plasma exchange procedures beyond 72 hours post partum in an effort to effect arrest and reversal of the HELLP process.[14] In an earlier published study of the 7 patients who underwent plasma exchange, it was emphasized that a trend of rising lactate dehydrogenase values in combination with a persistent or decreasing platelet count $<500,000/mm^3$ >72 hours postpartum usually represents atypical HELLP syndrome that will be responsive to plasma exchange therapy.[14]

Of all the potential, commonly available tests of liver dysfunction for the assessment and management of patients with HELLP syndrome, lactate dehydrogenase reliably demonstrates the most dramatic rise in serum levels. As a reflector of degree of hemolysis, as well as hepatic dysfunction, lactate dehydrogenase concentrations usually peak on the first postpartum day in class 2 patients and by the second postpartum day in class 1 patients. Mean values of platelets and lactate dehydrogenase for class 1 patients suggest that the downward trend in lactate dehydrogenase values begins at approximately the same time that the upward trend begins with platelet concentrations. Over time, lactate dehydrogenase values tend to be inversely proportional to the trend in platelet counts (Fig. 6). Such a trend and pattern are not as clear in the accumulated data from the less severely affected class 2 HELLP patients. In this latter group increased lactate dehydrogenase values appear to persist for a longer interval at a lower level than is the case with class 1.

The use of lactate dehydrogenase values in excess of either 500 or 600 IU/L as an index of disease severity is an arbitrary decision. The former value is utilized by hematologists at this institution for the monitoring of patients with thrombotic thrombocytopenic purpura, and the latter value is adapted from work by Sibai.[21] The percentage of patients with LDH concentra-

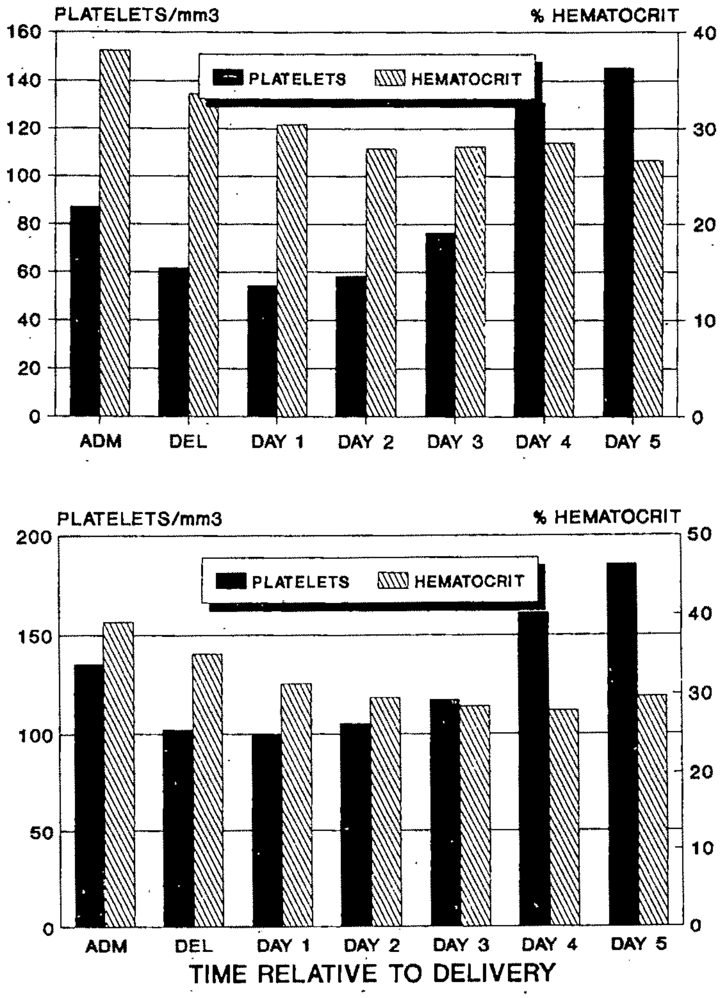

Fig. 8. Relationship between mean values of platelet count and hematocrit for all patients with class 1 HELLP syndrome *(top)* and class 2 HELLP syndrome *(bottom)*, demonstrated from hospital admission through fifth postpartum day.

tions > 600 IU/L on each peripartal day as illustrated in Fig. 5 appears to parallel the course of HELLP syndrome severity and could be a useful adjunct to patient management. Only patients who required plasma exchange therapy persisted in having lactate dehydrogenase concentrations in excess of 600 IU/L beyond the fourth postpartum day.

Aspartate aminotransferase appears to be the dominant transaminase released into the peripheral circulation with severe preeclampsia and HELLP syndrome.[4, 9, 26] Similarly, Catanzarite[22] observed a peak alanine aminotransferase/peak aspartate aminotransferase ratio of 0.55 in his series of 23 patients with class 1 and 2 HELLP. Not until late in the puerperium did serum concentrations of alanine aminotransferase exceed aspartate aminostransferase values in the present investigation. Importantly, high aspartate aminotransferase/alanine aminotransferase ratios were observed during the most active phases of the HELLP syndrome process. The dominance of aspartate aminotransferase relative to alanine aminotransferase was lost, and eventually the ratio reversed during the recovery phase of the disease.

Although microangiopathic hemolytic anemia underlies HELLP syndrome, paradoxically most patients are not anemic when first admitted to the hospital. The highest recorded mean hematocrit in this investigation was observed at hospital admission for both groups of patients. In both class 1 and 2 patient groups there was generally a downward trend in hematocrit after admission until the second postpartum day, after which a plateau effect was observed. It appears that hemolysis with secondary anemia is either arrested or effectively neutralized by hematopoiesis and red blood cell release, usually within 48 hours of delivery for patients with uncomplicated HELLP syndrome.

The natural history of HELLP syndrome as reflected by a variety of laboratory parameters has revealed its variety of presentation yet its relative predictability. The retrospective nature of this investigation precludes more definite hourly rates of rise and fall for laboratory parameters. Extensive prospective investigations of patients with HELLP syndrome could afford more definite assessment of disease status and improve guidance of therapeutic interventions so that the adverse maternal[4, 9] and perinatal[4, 9] effects (unpublished observations) of this "great masquerade" can be averted or minimized.

Discussion

DR. NORBERT GLEICHER, Chicago, Illinois. The article by Martin et al. represents a timely contribution to a still poorly understood clinical entity, initially described by Weinstein[1] in an astute clinical observation. Ever since, and once again in this article, the HELLP syndrome has been characterized as a multisystem disease form of severe preeclampsia-eclampsia. If one accepts this premise, then the HELLP syndrome may, in fact, contribute to our understanding of preeclampsia-eclampsia.

Martin et al. summarized 158 gravid women, after a retroactive review of patient charts for a period of 9 years 3 months, who qualified as HELLP patients. Whereas any such *retroactive* chart review has obvious shortcomings and has to represent a selection bias toward more severe cases, this nevertheless represents the largest number of patients with HELLP so far reported in the literature in a single study. In that aspect alone it represents a unique resource.

I would like to utilize this resource in attempting to point out two very important observations that did not receive the deserved attention in the authors' discussion. Both may, in my opinion, shed light on the pathophysiologic characteristics of preeclampsia-eclampsia. First, I was pleased to note that an unexpectantly high percentage of affected women were multiparous

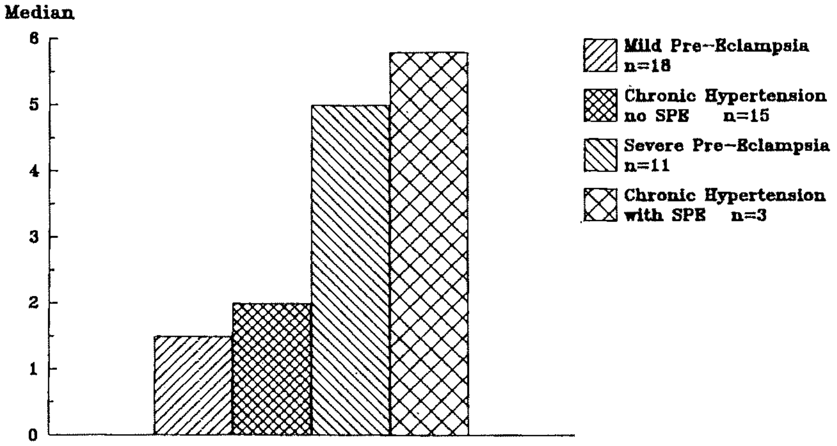

Fig. 1. Autoantibody positivities in hypertensive conditions of pregnancy.

(42%). On first impulse this should surprise, since preeclampsia-eclampsia is generally considered a disease of the primiparous woman. Second, the authors reported that HELLP abnormalities, such as thrombocytopenia and liver abnormalities, peak at 24 to 48 hours *after* delivery. This once again does *not* correspond with the reported classic natural history of preeclampsia-eclampsia, which suggests a return to normal within 24 hours from delivery.

What then can explain these observations? Martin and associates reported in an earlier publication that plasmapheresis improves HELLP parameters in otherwise nonresponsive patients in the postpartum period.[2] Other reports confirm this and also suggest a beneficial effect in the antepartum period, as so well reviewed recently by Watson et al.[3] Whereas plasmapheresis can remove a large variety of biologically active substances, there are reasons to believe that the culprits in HELLP are antibodies. Plasmapheresis is highly efficient in the removal of antibodies.[3] Antibodies to platelets have been reported in women with preeclampsia-associated thrombocytopenia.[4] Moreover, we[5] and others[6] have recently reported significant autoantibody abnormalities, and especially antiphospholipid antibodies, in patients with hypertensive diseases of pregnancy. Fig. 1 demonstrates that the number of autoantibody abnormalities increases with severity of maternal disease, if maternal disease is classified in accordance with Chesley's classification,[7] which correlates with adverse perinatal outcome. This figure also demonstrates that autoantibody abnormalities are not exclusively restricted to classically primiparous women with preeclampsia but also can be found frequently in multiparous women with chronic forms of hypertension. Therefore it was not surprising that Martin et al. reported such an unusually high incidence of multiparous patients among their HELLP population.

This then raises the question of from where the stimulating epitopes are derived. Once again, the study presented here may suggest an answer. The report that HELLP peaks 24 to 28 hours *after* delivery suggests that the causative epitopes reach maximal levels at or around the time of delivery. This is also the time period of largest fetomaternal cell "traffic." In an earlier presentation to this society, we have proposed that pregnancy be understood not only as an allograft but also as an autograft.[8] Maternal responses to self-components, derived from the fetus by fetomaternal cell "traffic," result in autoantibody production, which, if excessive, causes clinical autoimmune phenomena as seen in HELLP.

Under such a concept, HELLP is, in fact, an extreme form of preeclampsia-eclampsia but not necessarily in the traditional sense. Most likely, the patient with HELLP is extreme in either fetomaternal cell traffic or in genetic susceptibility to antigen self-stimulation, a concept also supported by recent reports of nonhypertensive HELLP. Last, under such a concept HELLP is only one among many *peripartal autoimmune syndromes,* characterized by peripartal exacerbation.

The authors have once again demonstrated that the investigation of extremes can further our understanding of the common in such poorly understood clinical situations as preeclampsia-eclampsia.

DR. STEPHEN S. ENTMAN, Nashville, Tennessee. I am delighted to see Dr. Martin and his colleagues present these data that further clarify this syndrome of multisystem organ failure. This article is important for two reasons. It expands our knowledge. Since Dr. Pritchard first alerted us to the hemolytic manifestations, we have tried to understand how to place the pieces into the practical puzzle of clinical care. Popularized as the HELLP syndrome, the diagnosis is now more frequently, consistently, and appropriately made. Dr. Martin and associates, in this work and in a previously published article on plasma exchange,[1] have begun to answer some of the important practical clinical questions.

The second reason that this article is important relates to the philosophy of how new techniques and technology are introduced into the literature and then into the practice setting. These are the data that provide the foundation to support the use of plasma exchange therapy in the postpartum patient. In contrast to other popularized techniques, there is a data base available on which to form judgments about who, when, what, and why to subject patients to the risk and expense of a procedure. All too often, we have had to retroactively fit the foundation of data to justify diagnostic or therapeutic procedures that have already entered the practice of medicine. A purist might prefer that this article have anteceded the one promoting postpartum plasma exchange, published in January 1990, it is clear that the authors understood the content of these data in formulating their previous work. Now, without having been prompted by criticism, they have brought it to the rest of us. For this approach, they are to be commended.

After reading the entire manuscript, I do have several points to raise and several questions of Dr. Martin. Would you explain the rationale for separating patients into class 1 and class 2? It seems to me that this is an artificial division of continuously distributed platelet data into dichotomous data. This is especially concerning with retrospective data that may or may not have been obtained at the peak of the clinical manifestations or at the nadir of the platelet count. Platelet counts reflect a continuum of severity of the syndrome. In fact, there is only minimal difference between the two groups in the shape of the curve illustrating time course to recovery. I would prefer that you highlight those patients who ended up with transfusion or plasma exchange. These are, in fact, the patients whom you are most interested in distinguishing because their clinical course was atypical. Your goal in educating us is to help us understand the criteria for intervention.

Regarding the demographics of the study group, in comparison with the rest of your patient base and those patients with pregnancy-induced hypertension who did not have HELLP, was the racial, maternal age, gestational age, and parity distribution of these patients noteworthy? Are you confident that all patients with this syndrome were identified? I raise this question because you report an average of only 20 cases per year; in contrast, in our institution we have 50 to 60 cases per year. This may be a function of the difference between criteria for a clinical diagnosis compared with those for a diagnosis for investigative purposes. Specifically, I refer to inclusion criterion number 3, which demands overt evidence of gross hemolysis, evidenced by falling hematocrit, or overt coagulopathy, evidenced by abnormal bleeding. In our experience these patients are uncommon. We have always found it difficult to assess hematocrit changes in the face of hemoconcentration, intravenous fluid replacement, peripartal bleeding, and subsequent fluid shift during recovery. I wonder if you have a sense of the frequency with which your patients with a clinical diagnosis of HELLP have not met the study criteria.

I would caution the authors to review the distribution of their data for enzymes. It is a common pitfall to apply parametric statistics to enzyme data, but the gross deviation of the data curve from normalcy results in quite misleading information. Analysis of variance tests the distribution of data but assumes comparable variance in the comparison groups. A nonparametric test such as the Mann-Whitney U test might be more appropriate since it makes no assumptions about the shape of the data curve.

I have a further question about the data on elevated enzymes. In the manuscript there was significant attention to the shifting ratio of aspartate aminotransferase/alanine aminotransferase. Could you elaborate on the implications of that shift? Also, although I recognize that these data were compiled retrospectively, I wonder if you have any information about lactate dehydrogenase isozymes.

In summary, this report contains important information for those of us practicing high-risk obstetrics. It helps us distinguish those patients who will have spontaneous recovery from those who will benefit from therapeutic intervention. Understanding this will have a positive effect on the health of perinatal patients.

DR. CHARLES A. STEDMAN, New Orleans, Louisiana. Did you have the opportunity to separate out the patients who had undergone cesarean section versus those who were delivered vaginally to see if there was any difference in the recovery phase?

Dr. Richard P. Perkins, Omaha, Nebraska. I basically wanted to ask the same question that Dr. Stedman did. Our own studies followed these same results pretty closely. I think it is hazardous to try to determine the natural history of a platelet count in a patient who has had a massive tissue injury, such as cesarean delivery. I would be interested in what your cesarean section rate was and whether there was any difference between the cesarean and vaginal delivery populations.

In our own series this disease occurs at a stage in the pregnancy where about 86% of women are delivered abdominally, and that doesn't leave very many patients for a true study of the natural history. I would also ask whether patients were excluded or otherwise accounted for who had, in fact, received platelet transfusions before the performance of cesarean section, if indeed you do those.

Dr. Carolyn B. Coulam, Indianapolis, Indiana. Like Dr. Gleicher, I'm intrigued with the multiparous population with HELLP syndrome and have three questions in that regard for Dr. Martin.

(1) How many patients in your series were multiparous? (2) Of the multiparous population, how many of these women had had previous pregnancies with HELLP syndrome? (3) How many of these multiparous patients were with the same partner that they previously had?

Dr. Paul G. Tomich, Maywood, Illinois. With regard to the thrombocytopenia, what percentage of patients in class 1 and class 2 had platelet transfusions? Were they predelivery or postdelivery transfusions?

Dr. Martin (Closing). I thank all the discussants for their questions. You will have to invite me back perhaps for some of the answers.

The first discussant, Dr. Gleicher, raised some questions about the immunology of this disorder. Certainly that is something that's been discussed by many people. An alternate explanation for the findings seen might be that they result from the ongoing reparative process after delivery. If one believes that HELLP syndrome develops as a sequela to a vascualr endothelium disruption process with prior oxidative damage to the endothelium and so forth, the recovery process would be expected to take several days.

Also, I would point out that 24% of the pregnancies in this study population were patients with recurrent HELLP. This includes many of the multiparous patients in this study.

Dr. Entman raised several excellent questions. He asked about the rationale that was utilized to develop the proposed classification scheme for HELLP syndrome. As we analyzed these data and treated these patients, it became very clear to us that there is a spectrum of disease for which there are no clear and absolute breaks in the data and thus no distinct groups. As I have lived and worked with these data for the last year or two, I have become convinced that the real break occurs at a platelet count of 50,000/mm^3. As the patient's platelet count falls below that amount, the amount of maternal morbidity increases substantially with a greater need for transfusions and more renal and pulmonary problems. Data regarding this were presented at the Tenth Annual Meeting of the Society of Perinatal Obstetricians, Houston, Texas, Janaury 23-27, 1990.

Did we identify all affected patients? I suspect we may have missed a few. The vicissitudes of medical record keeping and data collection preclude complete assurance that we identified every case. I think we studied just about every eligible parturient.

The ratio of aspartate aminotransferase to alanine aminotransferase was an incidental observation made in the concluding phases of data analysis. I do not know its significance.

Yes, we are looking currently at lactate dehydrogenase isozymes because the sixth lactate dehydrogenase isozyme is reportedly elevated in patients with particularly severe multisystem disease; at present I have no data to share.

A question was asked about neonatal morbidity and perinatal consideration. In a poster presentation at the Tenth Annual Meeting of the Society of Perinatal Obstetricians, our group reported that perinatal and neonatal problems increase in proportion to a worsening degree of HELLP syndrome. This is observed in relation to decreasing birth weight, lower Apgar scores, higher incidence of intraventricular hemorrhage, and so on. We did not find a consistent relationship with neonatal platelet counts.

Dr. Stedman and Dr. Perkins both raised the issue of whether mode of delivery could have an impact on recovery from disease. We have not analyzed our data on the basis of different modes of delivery. In this series 55% of our patients underwent cesarean delivery. Mode of delivery does not appear to have made a significant difference on disease pattern or recovery rate but we will go back and answer that question at a later time.

Dr. Coulam asked about the number of multiparous patients in this investigation. A total of 42% of the 302 patients, a larger percentage than we would have predicted, were multiparous. We reported at the Thirty-seventh Annual Meeting of the Soceity for Gynecologic Investigation, St. Louis, Missouri, March 21-24, 1990, that there were 94 subsequent gestations after class 1, 2, or 3 HELLP syndrome. Among these 94 there were 23 patients who had recurrence of HELLP syndrome, for a 24% recurrence rate. We have no data regarding the identity of sexual partners, so no conclusions can be derived regarding the same father versus a different father in a subsequent pregnancy.

Finally, Dr. Tomich asked about platelet transfusions, another excellent question. Our patients with class 1 HELLP syndrome received platelet transfusions in approximately 30% of cases. When we began the study, we were utilizing the practice of platelet transfusion when the maternal platelet count fell below 50,000/mm^3. We now know, and will report later this year in another presentation, that that cutoff point is probably too high because in our experience clinically significant bleeding does not occur until the platelet count decreases below 30,000/mm³. Therefore this value has become our cutoff point below which we protect patients with platelet transfusion whether they are to be delivered vaginally or abdominally. The overall incidence of transfusion is 60% in class 1 HELLP and 40% in class 2; virtually no patients in class 3 (platelet nadir >100,000/mm³ to ≤150,000/mm³) receive blood products.

We believe that the class 3 group requires further study. For practicing clinicians I think the class 3 grouping functions as a "bright yellow flag," prodding obstetricians to notice that patients are about to get into trouble as they fall into the class 2 and then class 1 grouping.

Suture entrapment and secondary ureteral obstruction

C. Robert Stanhope, MD, Timothy O. Wilson, MD, William J. Utz, MD,
Lynwood H. Smith, MD, and Peter C. O'Brien, PhD
Rochester, Minnesota

During the 6-year period ending in 1988, suture entrapment and secondary postoperative ureteral obstruction occurred in 18 (0.33%) of the 5379 patients who underwent major pelvic operations for benign conditions. Sixteen cases occurred after vaginal surgery and two after abdominal hysterectomy. Placement of the McCall suture or sutures for elevation of a bladder neck caused ureteral entrapment most frequently. Early diagnosis was facilitated by comparison of preoperative and postoperative serum creatinine levels. The mean change in serum creatinine level in patients with unilateral obstruction was an increase of 0.8 mg/dl. Treatment by either antegrade placement of ureteral stents or abdominal exploration with deligation or ureteroneocystotomy was successful in all cases. Retrograde placement of ureteral stents was unsuccessful. (AM J OBSTET GYNECOL 1991;164:1513-9.)

Key words: Postoperative ureteral obstruction, McCall's suture, high serum creatinine, percutaneous nephrostomy, antegrade ureteral stenting

Ureteral injury occurs infrequently after pelvic surgery for benign disease; however, the risk can be minimized by understanding the relationship of the ureter to other pelvic organs and, whenever possible, by identifying the ureter at operation. Identification and exposure of the ureter is readily accomplished during abdominal surgery because the retroperitoneal space can be entered easily and safely and the ureter can be identified throughout its course. This is not possible during vaginal surgery, especially if the course of the ureter is distorted by marked pelvic relaxation or previous pelvic surgery. We have reviewed our recent experience with ureteral obstruction after pelvic surgery for benign conditions to determine the frequency with which this occurs, to identify means for early diagnosis, and to describe our current management.

Patients and methods

In the 6-year period ending in 1988, 5379 major pelvic operations were performed for therapy of benign conditions at the Mayo Clinic. Of this group 2546 were vaginal hysterectomies or operations for correction of vaginal prolapse and 2833 were abdominal hysterectomies or other gynecologic abdominal operations for therapy of pelvic conditions. Eighteen cases of suture entrapment and secondary postoperative ureteral obstruction (15 unilateral and 3 bilateral) were found for an overall incidence of 0.33%. The obstructions were attributable to entrapment by ureteral ligation or ureteral kinking by the placement of a periureteral ligature. Ureteral perforation by a needle was not identified in any case. Sixteen cases occurred after vaginal operations, including repair of the vagina (incidence, 0.63%), and two occurred after pelvic operations done abdominally (incidence, 0.07%) (Table I). The site of

Right	6
Bilateral	3

obstruction was the distal ureter in each case; the left side was involved more often than the right (Table II).

Flank pain, fever, or both occurred in 13 patients (72%) in the immediate postoperative period, and difficult micturition was noted in two patients. No patient experienced hematuria. Bilateral involvement was promptly recognized by anuria in three patients.

Signs of unilateral ureteral obstruction within the first 36 to 48 hours included an early transient increase in serum creatinine value in 17 of the 18 patients; one patient did not have a postoperative serum creatinine determination within that interval. In the evaluable patients with unilateral obstruction, the mean serum creatinine value was 0.93 mg/dl before operation and 1.65 mg/dl at 36 to 48 hours after operation. The mean change in serum creatinine level in patients with unilateral obstruction was an increase of 0.8 mg/dl (range, 0.3 to 1.4 mg/dl). Excretory urography, percutaneous nephrostography, or renal pelvic ultrasonography was used to confirm partial or complete unilateral ureteral obstruction (Figs. 1 and 2).

Three age- and procedure-matched controls for each of 13 cases of unilateral ureteral entrapment were identified. Serum creatinine levels increased markedly more in the cases than in the controls ($p < 0.001$; two-tailed paired *t* test) (Fig. 3). In a number of instances in the control cases, the postoperative creatinine value decreased slightly, presumably related to operative and immediate postoperative hydration.

Etiology. Although the ureter can be palpated during vaginal surgery and excluded from the vascular pedicles, it easily can become entrapped by the suture used to ligate a pedicle, to repair descent of the bladder neck, or to plicate the uterosacral ligaments.

Plication sutures at the base of the bladder approximate the pubovesicocervical fascia and correct the bladder neck descent while restoring the posterior urethral vesicle angle. It is our practice to place at least one McCall's suture to plicate the uterosacral ligaments and to obliterate any potential enterocele space in every patient undergoing vaginal hysterectomy or repair of vault prolapse. Often, two or more McCall's sutures are placed when there is significant enterocele or marked vaginal vault prolapse.

At least one McCall's suture was used in every vaginal case; however, two were used in five cases and three sutures were used in three cases. Either the McCall

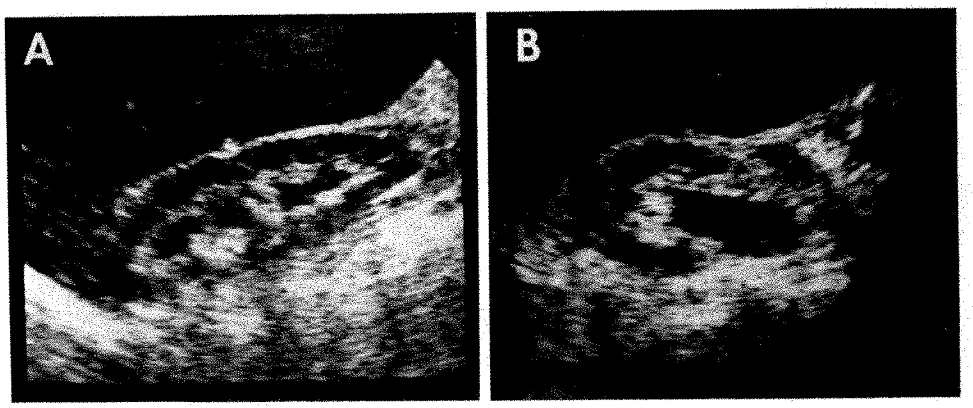

Fig. 2. Ultrasonograms of renal pelvis **(A)** and ureter **(B)**, demonstrating dilation of renal pelvis and ureter in association with ureteral obstruction caused by suture entrapment.

suture or the sutures used to repair bladder neck descent caused partial or complete obstruction in 14 cases. In one vaginal case a suture on a uterine artery pedicle caused entrapment, and in one vaginal case an infundibulopelvic ligament tie caused entrapment.

After abdominal hysterectomy a Moschcowitz uterosacral plication suture caused ureteral entrapment in one patient and a pelvic peritonealization suture caused entrapment at the pelvic brim in the second (Table III).

Rarely was the ureter actually encircled by a suture. Most commonly, the ureter was merely kinked by suture placement in the periureteral tissues.

Results

Attempted retrograde passage of a ureteral catheter at cystoscopy in 10 cases was unsuccessful. Retrograde ureteroscopy was attempted in one case but was not successful.

Percutaneous nephrostomy was performed in eight cases to achieve drainage of the affected renal unit, as well as to attempt antegrade passage of a ureteral catheter; subsequent stenting in this fashion was successful in six cases. Ten patients underwent early reoperation by the transperitoneal approach to mobilize the involved ureter(s) and, when indicated, to place ureteral stents through a cystotomy incision. Two patients required ureteroneocystostomy because the ureter was damaged or its vascular supply was compromised. Segmental ureterectomy and ureteroureterostomy were not indicated. No patient had a subsequent fistula, and all patients subsequently had normal renal function as measured by serum creatinine level. Subsequent excretory urography, performed in only a small group of patients, showed postoperative changes with no significant abnormalities.

Comment

The early recognition of ureteral obstruction is important because the degree to which nephron function is lost irreversibly is directly related to the duration and completeness of the obstruction. There are four areas within the pelvis where suture entrapment is most likely to occur: (1) the point where the ureter crosses the iliac vessels, (2) the point where the ureter comes into close proximity to the adnexa near the pelvic brim, (3) the point where the ureter is crossed by the uterine vessels, and (4) the base of the bladder where traction on the interureteric ligament may obstruct the ureter.

The relationship of the ureter to other pelvic structures during vaginal surgery has been examined during operating conditions.[1] The ureter is a mean of 1.0 cm from the clamp placed on the infundibulopelvic ligament when the tube and ovary are removed and a mean of 0.9 cm from the plication sutures used to provide support to the base of the bladder. However, despite this close proximity, ligation of the ureter or kinking is an uncommon occurrence. However, when it happens, it rarely is recognized during the operative procedure.

The frequency of postoperative ureteral obstruction reported in the literature ranges from 0.1% to 2.4%.[2-4] Most of the reported cases involve injury occurring during abdominal hysterectomy for benign conditions. The present study differs in that only rarely (2/18) did the injury occur during abdominal hysterectomy, and the vaginal surgery associated with injury involved uterine or vaginal prolapse in every case.

Early recognition of ureteral obstruction in the postoperative period, even before flank pain or fever develops, is possible by detecting subtle increases in the serum creatinine value, which can begin as early as 24 hours after operation. The serum creatinine value may return to nearly normal by 72 hours after operation. This phenomenon has been observed under experimental conditions in the case of unilateral ureteral obstruction.[5]

With total unilateral obstruction, initially there will be a transient increase in renal blood flow, lasting 1 to 2 hours. This will be followed by vaosconstriction and

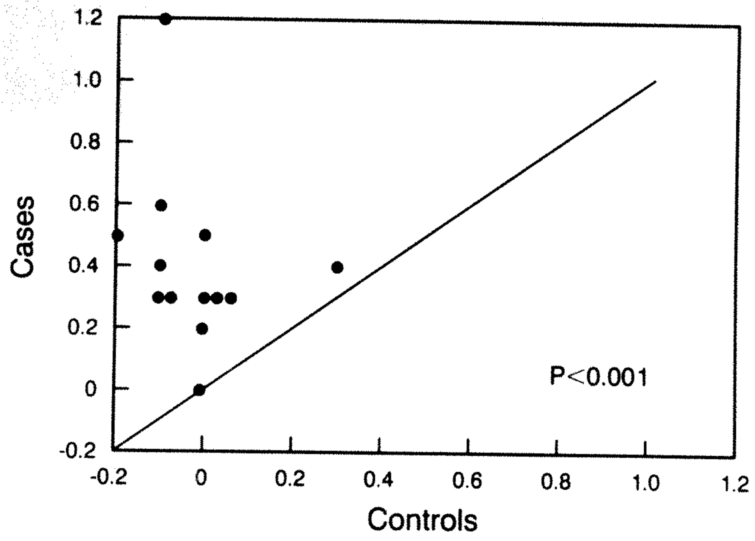

Fig. 3. Increases in serum creatinine level (milligrams per deciliter) were greater in 13 patients with unilateral ureteral obstruction *(Cases)* compared with mean of three age- and procedure-matched patients who had no obstruction *(Controls)* ($p < 0.001$).

*Six cases were treated successfully with antegrade placement of a ureteral stent, so cause was not determined.

a progressive decrease in renal blood flow with a decrease in glomerular filtration rate, which is marked by 24 hours. The situation is similar to that after nephrectomy—an initial increase in creatinine value and a slow decrease back to normal in a matter of weeks, as the contralateral kidney hypertrophies functionally.[6]

Historically, the first attempt at treatment was cystoscopy, retrograde pyelography, and attempted passage of a ureteral catheter or stent. Although retrograde pyelography has been useful to document the point of obstruction, this information is of little added clinical benefit. All 10 attempts to pass a ureteral stent (after retrograde pyelography) past the point of obstruction failed.

Ureteroscopy is a valuable new technique for the diagnosis and treatment of some cases of ureteral obstruction.[7] In some situations in which a catheter cannot be placed cystoscopically, endoscopic inspection usually can identify the site of obstruction through which a wire or stent can be passed. This procedure was attempted in one patient but was not successful. Additional experience with this procedure may be useful.

Early percutaneous nephrostomy is advisable to provide drainage of the renal unit and to preserve renal function. This obviously is significant with bilateral obstruction, but it is also important with unilateral obstruction. An antegrade ureteral stent was passed successfully 24 to 48 hours later in six of eight attempts in cases of unilateral obstruction. When antegrade ureteral stent placement was not successful, the exact nature of the entrapment was determined and the ureter(s) was released surgically.

The issue of immediate reoperation in the early postoperative period or delayed operation remains controversial. After percutaneous nephrostomy, a "wait-and-see" approach without stent placement has been advocated[8] when ureteral obstruction is secondary to entrapment by an absorbable suture. On the basis of our experience, if antegrade stent placement is not possible, early exploration has been well tolerated and well accepted by our patients without occurrence of ureteral fistulas or loss of renal function.

In conclusion, the nature of pelvic surgery and the many anatomic variations encountered create a setting in which suture entrapment and secondary ureteral obstruction can occur, regardless of the experience of the surgeon. Four conclusions can be drawn from our experience.

1. Small increases in serum creatinine level 36 to 48 hours after pelvic surgery suggest postoperative unilateral ureteral entrapment.

2. Suspected abnormalities should be confirmed with either excretory urography, percutaneous nephrostography, or ultrasonography of the renal pelvis and ureter; the latter is an extremely sensitive, noninvasive pro-

cedure that is not dependent on renal function or dynamic renal scanning. Retrograde pyelography and attempts at retrograde placement of ureteral stents are not successful; however, ureteroscopy may make it possible to place a stent proximal to the obstruction.

3. Percutaneous nephrostomy to drain the kidney should be performed early, and antegrade pyelography with placement of a ureteral stent is desirable.

4. Abdominal exploration with ureteral mobilization is needed when a stent cannot be passed beyond the point of obstruction or the kidney cannot be drained adequately. Removal of the offending suture(s) or ureteroneocystostomy is indicated to avoid loss of renal function or further problems, such as fistula formation.

Discussion

DR. BRUCE H. DRUKKER, East Lansing, Michigan. Once again our colleagues from the Section of Gynecologic Surgery at the Mayo Clinic have tapped their substantial surgical experience and provided us with interesting material for comment, speculation, and inquiry.

The fact that approximately 900 pelvic procedures per year for benign disease were done during the 6-year study period exemplifies the magnitude of the resource, and the low occurrence of entrapment (0.33%) focuses on the excellence of technique of these high-volume gynecologic surgeons.

Ureteral entrapment is a concern for all gynecologic surgeons. This article focuses on the interesting observations of renal physiologic change, which are useful for diagnosis, and on the fact that almost all of the entrapment situations occurred during vaginal surgery. Further, it appears that the so-called McCall suture, singly or in multiples, or suture to repair bladder neck descent, was the offending suture in at least eight of 18, or 44%, of cases. One can speculate that some other entrapments were also due to these sutures; however, that diagnosis could not be confirmed because of the passage of a percutaneous ureteral stent. Could the authors tell us which suture sequence, the McCall or that used for bladder neck descent correction, caused entrapment more frequently? Although entrapment occurred infrequently in these cases, it did occur in 0.63% of vaginal cases compared with only 0.07% of abdominal cases. Why is this? Do Dr. Stanhope and his colleagues routinely expose the ureter in all pelvic procedures for benign conditions? If they do, what does that really mean—"to expose"? Is the peritoneum lateral to the ovarian vessels opened? Is the broad ligament opened to reveal the ureter? Is the dissection carried lower into the so-called cardinal ligament area? The reason I ask is because "to expose" means different things to different people. With respect to the vaginal cases, ureteral exposure, of course, is not routine and the ureter generally is not noted. However, the adage of "staying close to the uterus" seems to save most of us from damaging the ureter. On the other hand, particularly in vaginal hysterectomy for grade II or grade III prolapse, there are a few gynecologic surgeons who say you can routinely palpate the ureter. Most of us probably are somewhere in between. If there is a potential problem with the McCall suture and its use continues, as I suspect it does, what precautions are taken to avoid this problem? Has the suture been placed differently or are different clamps used? Certainly, the Haney clamp does take a stout amount of pedicle tissue.

But let's go on to some more valuable material. The authors cite an interesting reference evaluating the relationship between renal blood flow and ureteral pressure during an 18-hour period of total unilateral ureteral occlusion. This citation of basic science is particularly intriguing because it appears to be the clue the authors followed that suggests that transient 24- to 72-hour increases in serum creatinine do, in fact, occur after unilateral ureteral entrapment. This observation can lead to early suspicion of entrapment, and, as recommended by the authors, prompt, early treatment may salvage some renal glomerular units. Serum creatinine is a fairly standard preoperative assessment, but what triggered Dr. Stanhope and his colleagues to obtain postoperative creatinine assessments? Was it fever or flank pain? Or do they routinely order this study in all patients undergoing benign gynecologic surgery? That thesis is unlikely but possible. Since fever can occur from other sources in the immediate postoperative period, it seems flank pain would have been the discriminating system. I am sure the authors will shed some light on this. I would also like to know how they monitor recovery of damaged renal units and how one can determine return to normal function. In this situation creatinine seemingly is not helpful because the opposite kidney takes over function quite quickly. Did they evaluate creatinine clearances in these patients?

Now, to the next observation. Retrograde cystoscopically guided ureteral catheter placement does not seem to be very effective treatment for this problem, having failed in 10 attempted cases. On the other hand, six of eight patients underwent successful percutaneous nephrostomy with ureteral catheter placement. It appears that this is the way to go in the future. Have the authors now abandoned attempted retrograde ureteral catheter placement on the basis of their past experience, or do they feel it should at least be given a try? If it is effective, do they feel that a double J stent placed in a retrograde fashion does a better job than the percutaneous procedures? Also, when percutaneous catheters were inserted, what indicator was used relative to the time of removal? Were the indicators for removal the same as for those stents placed at the time of abdominal reoperation when the stent was placed by open cystotomy?

Dr. Stanhope and his colleagues have given us some interesting material to consider, but by this article they call to our attention that care should be taken to understand the anatomic characteristics of the ureter, particularly in patients with severe uterine or vaginal prolapse. Basic gynecologic surgery should not be taken for granted. It is an art that can be learned and practiced but periodically should be reassessed.

Congratulations to Dr. Stanhope and his colleagues for giving us some important information relative to serum creatinine and ureteral anatomy. It is a contribution that will help all of us.

Dr. Robert E. Rogers, Indianapolis, Indiana. When I review an article concerned with a surgical complication, I generally ask two questions: (1) How may I avoid the complication in my practice? (2) If I am faced with the complication, how is it diagnosed and treated? The answer to the first question is not in the purview of this study, but there are answers here.

Ureteral injury is avoided by ensuring that the operative site is fully exposed, adjacent organs are localized, and hemostasis is established by clamping and suturing structures that are identifiable and visible. In the study group at abdominal operation, when the surgeon was able to expose and identify the ureter, only two ureteral injuries were found in 2833 operations. One injury was related to pelvic peritonealization and another to a Moschcowitz cul-de-sac obliteration. One might speculate that these might have been avoided if the pelvic peritoneum had not been closed and if the cul-de-sac had been closed with a Halban[1] procedure. Nevertheless, this is an excellent record.

Sixteen injuries incurred in the course of 2546 vaginal operations should serve as a warning to those of us who treat increasing numbers of women with genital prolapse. Genital prolapse distorts pelvic anatomic relationships and places the ureter in harm's way. The solutions to this continuing problem await further study, but the authors have reminded us of the danger of the McCall culdoplasty. Their findings confirm the fact that when the ureter cannot be fully identified and exposed and pedicles isolated, injury will occur.

The low injury rate in abdominal operation is a testament to the ability of this group of surgeons to identify and isolate the ureter. Most reports[2] of ureteral injury state that three fourths of all ureteral injuries result from abdominal surgery whereas one fourth result from vaginal surgery. In this series the predominance of injury at vaginal operation is undoubtedly related to the demand for the care of complex genital prolapse.

The authors describe a laboratory test that points to a diagnosis of operative ureteral injury. The study is well conceived and well controlled, and the results are conclusive. I was surprised at the result. I have long believed that renal reserve was so great that the loss of function of one kidney in the presence of a contralateral normal kidney was of little physiologic consequence, even in the short term. The studies of Moody et al.[3] in dogs have shown that ureteral obstruction is followed by a transient increase in renal blood flow, followed by vasoconstriction and then a decrease in renal blood flow. In the early days after ureteral injury the increased requirement for filtration cannot be immediately met by the healthy kidney, and the result is a transient increase in creatinine. A transient rise in serum creatinine levels within 36 to 48 hours after operation is highly suggestive of ureteral obstruction. Thus the authors have taken an interesting laboratory observation and turned it into what may be a useful clinical tool. When these warnings are heeded, it will allow the surgeon to evaluate the urinary tract for injury early enough to save a kidney.

I am convinced that ureteral obstruction elevates creatinine levels postoperatively after 36 and 48 hours. My only concern is for the utility of the information. The problem is that many of us do not measure serum creatinine levels preoperatively, and if we did, measurements most likely would not be repeated postoperatively unless the patient was having postoperative problems.

It appears that the study group consists of patients with established ureteral injury who were studied retrospectively in regard to creatinine status. Did the authors review the results of creatinine studies in asymptomatic patients, seeking patients with asymptomatic (silent) ureteral injury, which in some studies account for >50% of the injuries?

Does the author feel that the test he describes is sufficiently useful that paired creatinine levels should be collected on all pelvic surgical patients?

Dr. Pedro A. Poma, Melrose Park, Illinois. I have two questions. First, did the authors review all the other cases of elevated creatinine, follow them, and find out how many *had* ureteral obstruction? Second, what is the influence of dehydration, blood loss, and fever in relationship to the postoperative creatinine levels?

Dr. Daniel Rightmire, Springfield, Illinois. I wanted to ask how often do the authors believe that unilateral entrapment of the ureter goes undetected, because that's certainly important in this case. Second, may I suggest that the change in serum creatinine data be submitted to receiver operating characteristic curve analysis?

Dr. Stanhope (Closing). I would like to thank Drs. Drukker and Rogers and Drs. Poma and Rightmire from Illinois for their comments.

Concerning Dr. Drukker's first concern, the probable and more likely site for ureteral entrapment is compression of the interureteric ligament. The McCall suture also has been documented to cause entrapment, and I have taken photographs of this. But I believe the greatest risk is traction on the interureteric ligaments, causing the ureter to kink.

The McCall suture, as described in 1957 and published in the *Green Journal,* consisted of three silk sutures designed to approximate the uterosacral ligaments from their posterior and lateral perirectal positions. If you draw an imaginary transverse line, bisecting the surgical field, and place the sutures well below that line, you can be reasonably assured entrapment will not occur.

Dr. Drukker's second concern was how we expose the ureter during abdominal operations where the ovaries or just the uterus is removed. It is our practice to open the broad ligament and identify visually the course of the ureter down to where the uterine artery crosses it. Then, when a clamp is placed on the uterus at the level of the uterine artery, we palpate the ureter. We do this in every case.

This report just dealt with surgery for benign conditions. However, our frequency of ureteral entrapment or obstruction after surgery for malignant conditions is less, related to the fact that most surgery for cancer is abdominal and the ureter is often completely dissected in cancer operations.

Finally, about retrograde ureteral studies, we don't attempt retrograde stent placement at all anymore. But there is a new procedure, called ureteroscopy. With a fiberoptic instrument the urologist can get into the ureter, advance a guide wire that can turn and maneuver around an apparent kink, and position a ureteral stent. Ureteroscopy may play a future role.

Dr. Rogers had expressed concern about obtaining serum creatinine levels. Serum creatinine levels were obtained preoperatively in all of our patients as part of our preanesthetic medical evaluation. We get postoperative electrolyte studies that also include serum creatinine. So, for a number of years, we have had this information available for both the preoperative and the postoperative periods.

I believe that this test is significant, with a high observed sensitivity of 100% and an observed specificity of 92%, and that we should obtain paired serum creatinine levels preoperatively and postoperatively, as you indicated, in patients undergoing hysterectomy or surgery where ureteral injury could occur. I think we should follow through on this.

Dehydration can cause an increase in the serum creatinine level. Serum creatinine may be elevated in the preoperative period when the patient has fasted, and then postoperatively, after hydration, it may be lower than the preoperative value.

Obviously, there are other causes for elevated creatinine, for example, the use of aminoglycosides.

I think that in our series there are probably undetected incidences where ureteral entrapment has occurred. We were not trying to look at that. We got the idea for this study from a nephrologist who indicated that this phenomenon occurred in patients who had unilateral ureteral stones and that these patients were found to have transient rises in serum creatinine. I noted that we frequently saw a rise after ureteral entrapment from vaginal surgery, so we decided to look at this in more detail.

I will take your suggestion for further statistical analysis.

Stage IB squamous cell cancer of the cervix: Clinicopathologic features related to survival

Michael P. Hopkins, MD, and George W. Morley, MD
Ann Arbor, Michigan

Three hundred forty-five patients with stage IB squamous cell carcinoma of the cervix were treated at the University of Michigan Medical Center from 1970 through 1985. The overall cumulative 5-year survival was 89%. The clinical characteristics included mean age 44.6 years, nulliparity 10%, married 93%, obese 38%, hypertension 32%, diabetes mellitus 5%, smoking 54%, symptoms of bleeding 68%, positive cytologic smear 83%. Lymph nodes were diseased in 45 of 261 (17%) with 26 unilateral (10%) and 19 bilateral (7%). Tumor differentiation showed: grade 1, 112 (33%); grade 2, 144 (42%); grade 3, 86 (25%). Factors that did not influence survival included age, presence or absence of positive cervical cytologic smear, the interval from previous papanicolaou smear, hypertension, smoking history, patient's blood type, and transfusion at radical hysterectomy. In all patients survival was significantly influenced by the following features: tumor classified as well differentiated (95%) or poorly differentiated (82%); tumor size <3 cm (91%) or >3 cm (76%); negative lymph nodes (93%) or positive lymph nodes (61%). When three or fewer lymph nodes were involved, the survival was 79% compared with 33% when four or more lymph nodes were involved. In 213 patients undergoing radical hysterectomy the cumulative 5-year survival was significantly influenced by the amount of residual cervical disease: no residual disease, 100%; <50% penetration, 96%; >50% penetration, 83%. Involvement of the lower uterine segment reduced survival to 73% compared with 95% when the lower segment was uninvolved. One hundred seventeen patients without angiolymphatic invasion had a 97% cumulative 5-year survival whereas 70 patients without disease in the lymph nodes but with angiolymphatic invasion had an 88% cumulative 5-year survival rate. A Cox model, multiple proportional hazard analysis was performed for all patients, and the factors that influenced survival included tumor grade, tumor size, presence of metastatic disease in the lymph nodes, and diabetes mellitus. In patients undergoing radiation therapy, the tumor grade and size were significant factors in survival. In patients undergoing radical hysterectomy, survival was influenced by the depth of cervical penetration and lower uterine segment involvement whereas the tumor grade, tumor size, patient's age, and removal of ovaries were not significant. (AM J OBSTET GYNECOL 1991;164:1520-9.)

Key words: Cervix cancer, squamous cell cancer

The survival in early stage invasive squamous cell cancer of the cervix is influenced by a number of features.[1-9] These are important from a prognostic standpoint but oftentimes do not alter the standard therapy of either radiation or radical surgery. As effective adjuvant therapies become available, these prognostic factors will be critical to determine which patients would benefit from adjuvant therapy. This study was undertaken to evaluate the clinicopathologic features related to survival in patients with stage IB squamous cell cancer of the cervix.

Material and methods

The clinical records, pathology reports, and gynecologic tumor conference notes for patients at the University of Michigan Medical Center with a diagnosis of carcinoma of the cervix for the period 1970 through 1985 were reviewed. The information for the clinical presentation, medical history, treatment modality, and size of the cervical lesion were recorded. All patients had staging of cancer according to the International Federation of Gynecology and Obstetrics (FIGO) guidelines. Patients with squamous cell carcinoma diagnosed after a standard hysterectomy without obvious parametrial involvement were considered to have stage I disease. These patients ($n = 21$) were only considered in the overall survival analysis. Microinvasive squamous cell carcinoma (stage IA), as previously reported from our institution, was defined as ≤3 mm of invasion without angiolymphatic invasion.[10] All patients with invasion >3 mm or angiolymphatic invasion were considered to have stage IB disease.

The original hematoxylin and eosin slides were reviewed. When the original slides were unavailable, the original pathology report and the gynecologic tumor conference note were utilized. All patients with an adenocarcinoma or adenosquamous carcinoma were excluded. Well-differentiated tumors were defined as those neoplasms where there was little nuclear pleomorphism and the nuclear cytologic atypia was not pronounced. Cells were generally large with abundant cytoplasm and a more normal nuclear/cytoplasmic ratio. In general, the well-differentiated tumors produced keratin, and mitotic figures were infrequent. Poorly differentiated tumors had pronounced nuclear pleomorphism, hyperchromatic nuclei, and scant cytoplasm. Cells were smaller, mitoses were frequent, and keratin formation was usually absent. Moderately differentiated tumors were intermediate in characteristics.

Only the patients who underwent radical hysterectomy were included in the survival analysis for the features of depth of penetration, angiolymphatic invasion, and lower-segment involvement. All these features were not known with certainty in patients who underwent radiation. The depth of invasion was measured by the residual disease in the hysterectomy specimens. Approximately 12 longitudinal sections through the cervix and lower uterine segment had been made at the time of the initial surgery. Thus the cervix, endocervix, and lower segment could be evaluated. Light microscopy of the slide with the maximum depth was used to evaluate the amount of residual disease. When necessary, a micrometer was used to determine if the lesion invaded >50% into the cervix. The lower segment was considered to be involved when disease extended into areas of endometrial stroma or glands. The mean number of lymph nodes removed at the time of pelvic lymph node dissection was 24. Lymph nodes were routinely cut into three sections for review.

Statistical analysis was performed by the Department of Biostatistics, School of Public Health, University of Michigan. Survival was plotted with the life-table method described by Kaplan and Meier.[11] The Savage (Mantel-Cox) method was used to test differences in survival.[12,13] A Cox model, stepwise proportional hazard analysis was used to compare the hazard for tumor-related deaths related to potential risk factors.

Results

During the time period 1970 to 1985, 345 patients with stage IB disease were identified. The overall cumulative 5-year survival was 89%. There was no difference in survival between those treated with radical surgery and those who received radiation therapy. The clinical characteristics included a mean age of 44.6 years (range, 18 to 89 years). Parity was available on 334 patients; 35 (10%) were nulliparous, 53 (15%) had one child, 257 (75%) had more than one child. Three hundred twenty-two (93%) were married, 132 (38%) were considered to be obese as defined by 20% above ideal body weight for height, hypertension was present in 109 (32%), and diabetes was present in 18 (5%). A smoking history was available for 320 patients, and 174 (54%) smoked within 1 year of diagnosis. Bleeding as a presenting symptom was present in 232 (68%), and 248 (83%) had a positive cytologic smear leading to the diagnosis. A previous, normal cytologic smear had been obtained within ≤1 year in 145 (47%), whereas 82 (30%) had not had cytologic testing performed in >3 years. The previous normal cytologic smears were not available for review. Oral contraceptives were used by 55 of 148 patients (37%) under age 40. The lymph node status was available on 261 patients with stage IB disease: 216 (83%) were negative, 26 (10%) had unilateral positive nodes, and 19 (7%) had bilateral positive nodes. Tumor differentiation was available for 342 patients: 112 (33%) had grade 1 tumors, 144 (42%) had grade 2 tumors, and 86 (25%) had grade 3 tumors. Size was evaluated according to those patients who had lesions ≤3 cm in size versus those whose lesions were >3 cm. Two hundred eighty-three patients (82%) had tumor size ≤3 cm whereas 61 (18%) had a tumor size >3 cm.

Radical hysterectomy was performed on 25 patients with invasion between 3 and 5 mm and 5 patients with <3 mm of tumor invasion but with angiolymphatic invasion. None of these 30 patients had node metastases and none has had a recurrence.

A survival analysis was performed for all patients. Factors that did not influence survival included age, the presence or absence of positive cervical cytologic smear, the interval from previous Papanicolaou smear, presence of hypertension, a history of smoking, patient's blood type, and whether transfusion was done at the time of radical hysterectomy. When all patients with stage IB disease were evaluated, the factors that significantly influenced survival included tumor trade, size of lesion, node status, and presence of diabetes. Patients with well-differentiated tumors had a 95% survival compared with an 82% survival in those with poorly differentiated tumors (Fig. 1). Patients with tumor size <3 cm had a 91% cumulative 5-year survival compared with a 76% cumulative survival in those with >3 cm (Fig. 2). The lymph node status was available for 261 patients, 213 of whom underwent radical hysterectomy with pelvic node dissection. Fourteen patients underwent surgical exploration for radical hysterectomy but did not have the surgery completed. The remaining patients had lymphangiography with directed needle biopsy for evaluation of lymph nodes. Patients without diseased lymph nodes had a 93% cumulative survival,

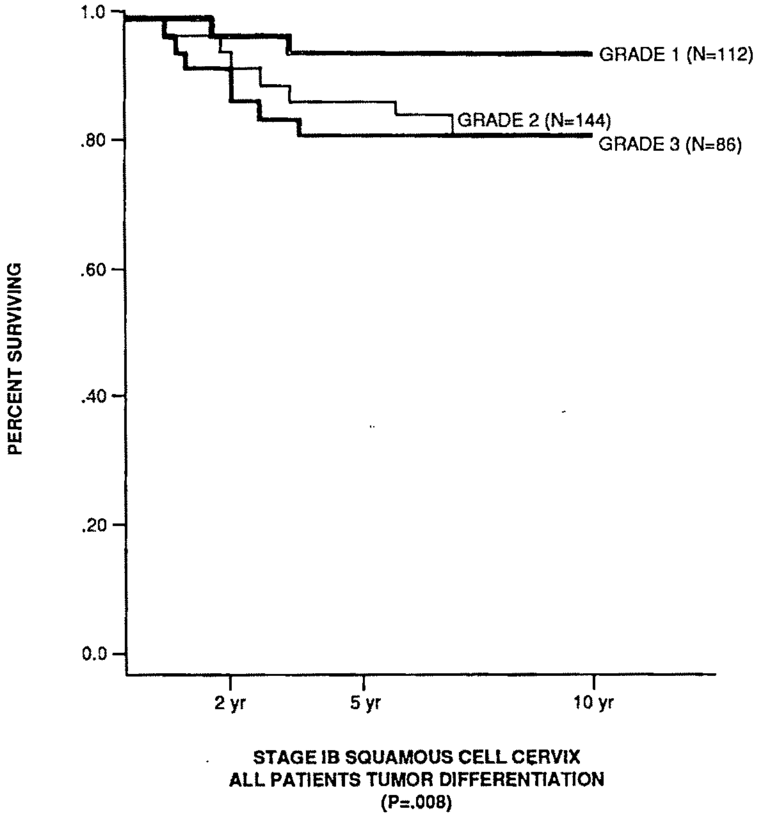

Fig. 1. Survival for all patients with stage IB disease according to tumor grade.

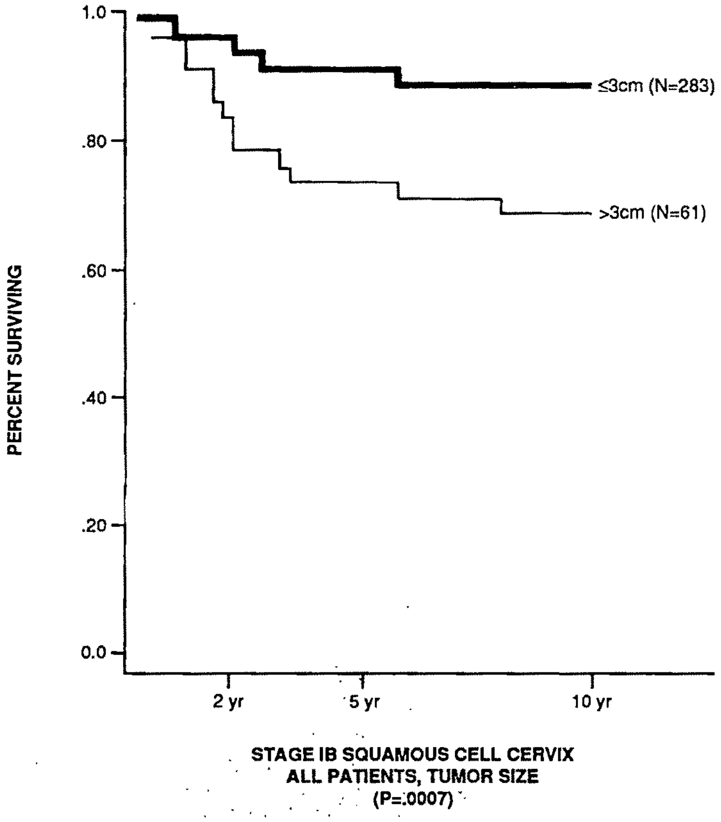

Fig. 2. Survival for all patients with stage IB disease according to tumor size.

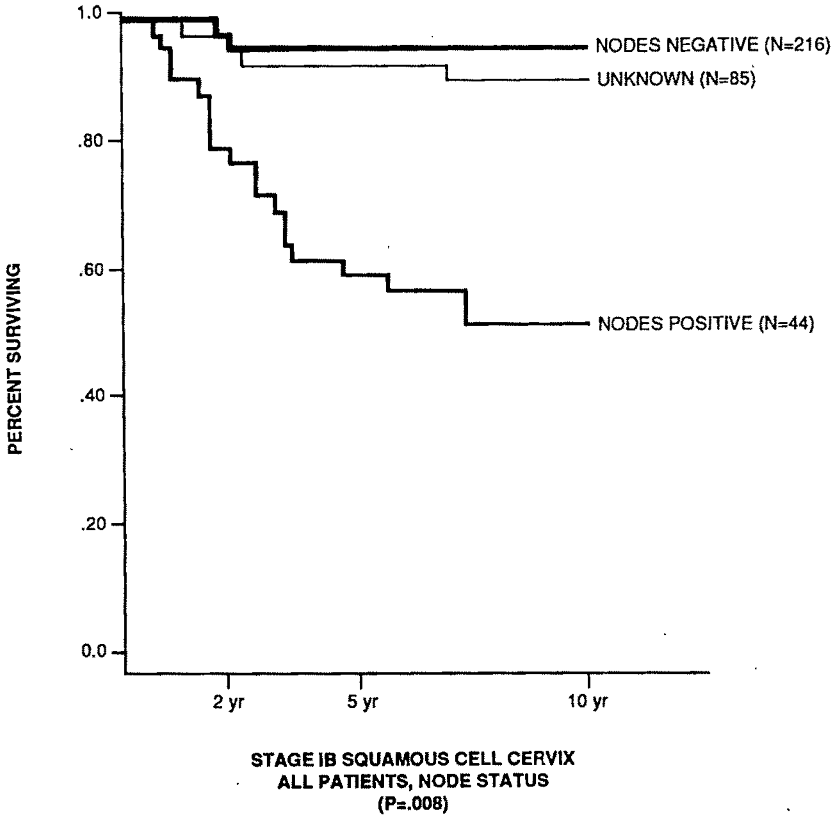

Fig. 3. Survival for all patients with stage IB disease according to lymph node status.

85 patients with an unknown lymph node status had a similar 5-year survival, and patients with lymph node metastases had a cumulative 5-year survival of 61% (Fig. 3). The patients with diseased lymph nodes were evaluated according to the number of lymph nodes involved. Patients with three or fewer involved lymph nodes had a 79% cumulative 5-year survival, whereas those with more than three involved lymph nodes had a 33% cumulative 5-year survival (Fig. 4). The presence of unilateral or bilateral lymph node metastases influenced survival. The patients with unilateral metastatic disease had a 75% cumulative survival, and those with bilateral metastases had a 42% cumulative survival. When all patients were evaluated, diabetes influenced survival. Eighteen patients with diabetes had an 82% cumulative 5-year survival compared with 327 patients without diabetes who had an 89% survival ($p = 0.04$). Patients with diabetes were generally older, were in poorer medical condition, and were more likely to undergo radiotherapy.

Patients who underwent radical hysterectomy were then evaluated. The depth of cervical penetration had a significant influence on survival. Additionally, the depth of penetration significantly influenced the chance of node metastases (Table I). Patients with no residual disease in the cervix at the time of radical hysterectomy had a 100% cumulative 5-year survival. Patients with <50% penetration had a 96% cumulative survival whereas those patients with ≥50% penetration had an 83% cumulative 5-year survival (Fig. 5.) Involvement of the lower uterine segment significantly influenced survival. When the lower segment was involved, survival was 73% compared with 95% when it was not involved (Fig. 6).

The significane of angiolymphatic invasion for survival was evaluated for those patients who underwent radical hysterectomy and had negative lymph nodes. One hundred seventeen patients without angiolymphatic invasion had a 97% cumulative 5-year survival whereas 70 patients without diseased lymph nodes but with angiolymphatic invasion had an 88% cumulative 5-year survival (Fig. 7). Radiation therapy was added in 10 patients with angiolymphatic invasion and this did not influence survival. An evaluation of survival according to the amount of residual tumor in the radical hysterectomy specimen was performed for the 70 patients with angiolymphatic invasion. Patients with angiolymphatic invasion but without residual disease in the cervix had a 100% cumulative 5-year survival. Patients with less than half of the cervix involved but with angiolymphatic invasion had a 94% cumulative 5-year survival whereas patients with angiolymphatic invasion and cervical penetration of ≥50% had a 78% cumulative 5-year survival (Fig. 8).

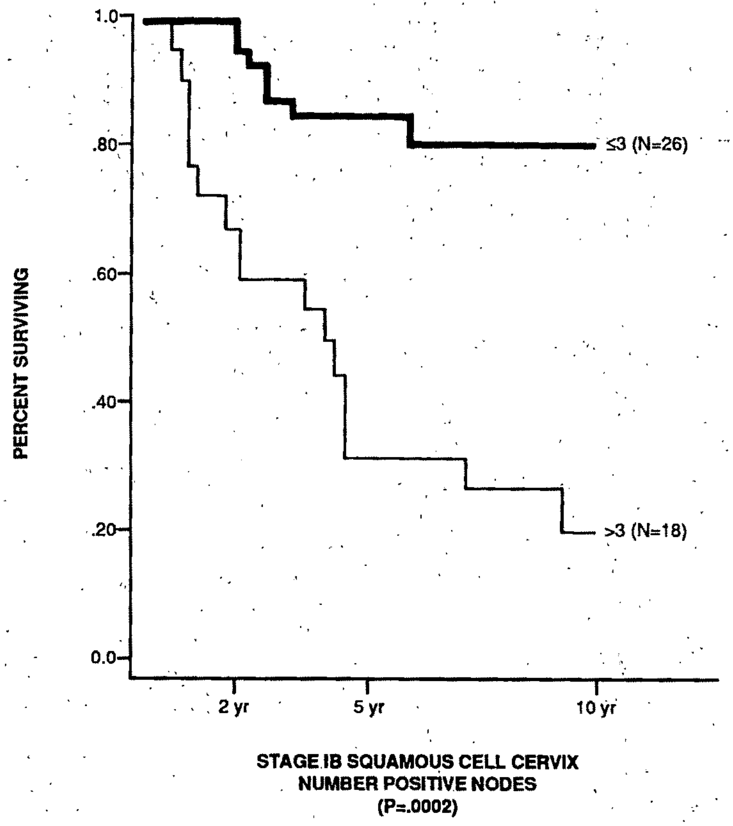

Fig. 4. Survival for all patients with stage IB disease according to number of lymph nodes with metastatic disease.

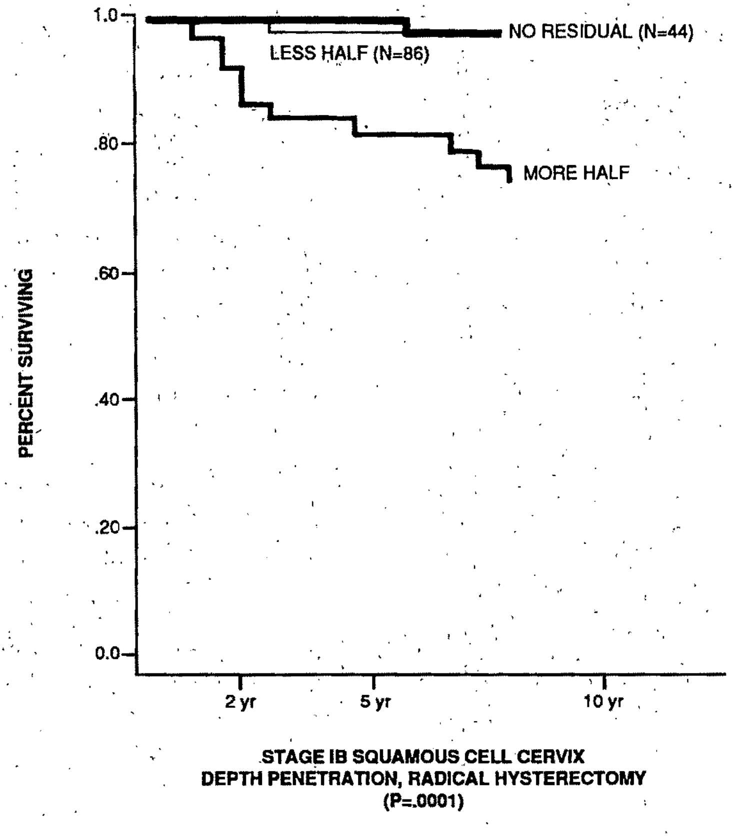

Fig. 5. Survival for patients undergoing radical hysterectomy according to depth of cervical penetration.

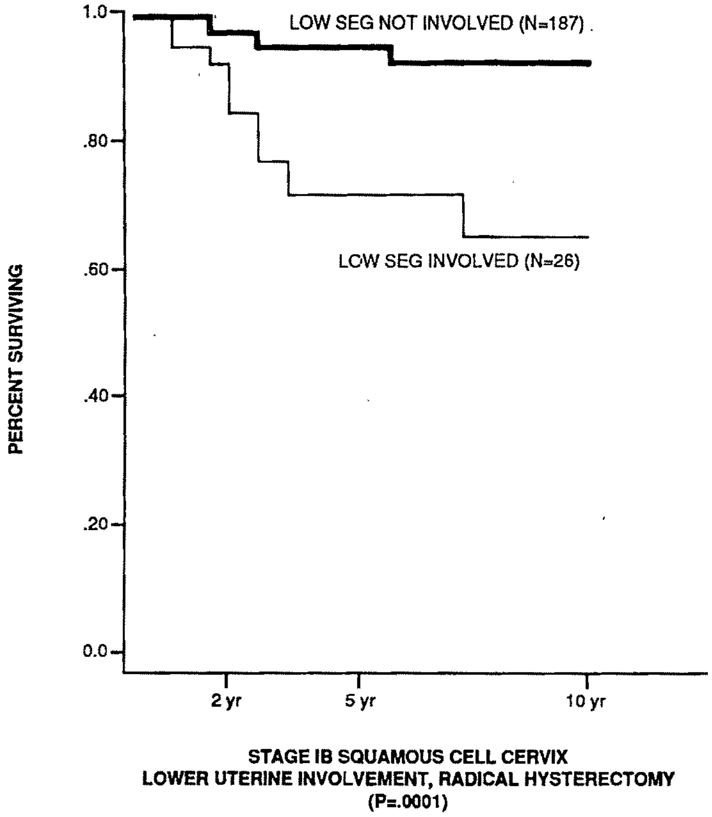

Fig. 6. Survival for patients undergoing radical hysterectomy according to presence of disease in lower uterine segment.

A Cox model, multiple proportional hazard analysis was performed for various subsets. When all patients were analyzed, the factors found to significantly influence survival included the tumor grade, size of the cervical lesion, presence of metastatic disease to the lymph nodes, and diabetes. Factors that did not influence survival included the patient's age, the interval since the previous cytologic smear, the finding of a positive cytologic smear, or a history of smoking. A Cox model analysis was performed only for those patients who underwent radical hysterectomy. In these 213 patients the factors found to significantly influence survival included a depth of cervical penetration of ≥50% ($p = 0.0001$); lower-segment involvement approached significance ($p = 0.06$). The tumor grade, tumor size, and age of the patient were not significant in the Cox model. The lymph node status was not significant in the Cox model, and this was due to the greater number of patients who had positive nodes when the depth of cervical penetration was considered. A Cox model analysis was performed for patients who underwent radical hysterectomy and had negative lymph nodes. In this model the depth of cervical penetration ($p = 0.001$) and the presence of angiolymphatic invasion ($p = 0.001$) significantly influenced survival whereas grade, size, age, and lower-segment involvement did not. In a Cox model analysis performed for patients undergoing radiation therapy the tumor grade and tumor size were significant for survival.

Table I. Node status according to amount of residual disease in cervix at radical hysterectomy ($p < 0.0001$)

Cervix	*Negative nodes*	*Positive nodes*	
		≤3	*≥4*
No residual	43	1	0
<50% Penetration	84	2	0
≥50% Penetration	60	16	7

Comment

The effect of tumor differentiation in squamous cell cancer has been evaluated with variable results. In our previous experience, as well as in this report, patients with a poorly differentiated histologic type had a decreased survival. In the previous time period, 87% with a poorly differentiated lesion survived to 5 years while 82% survived during the current time period.[14] Creasman et al.[3] found no difference in survival on the basis of tumor grade. Gauthier et al.[6] did not find the grade to be significant in 100 radical hysterectomy specimens evaluated. Underwood et al. found that survival dropped to 74% for patients with poorly differentiated

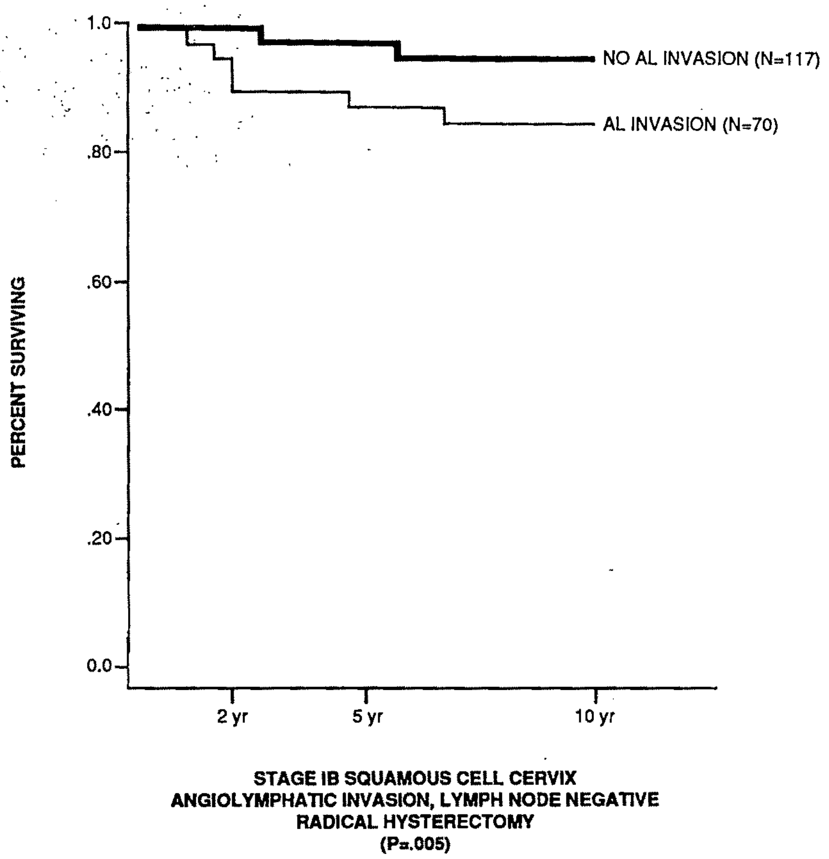

Fig. 7. Survival for patients undergoing radical hysterectomy with and without angiolymphatic *(AL)* invasion, with negative lymph nodes.

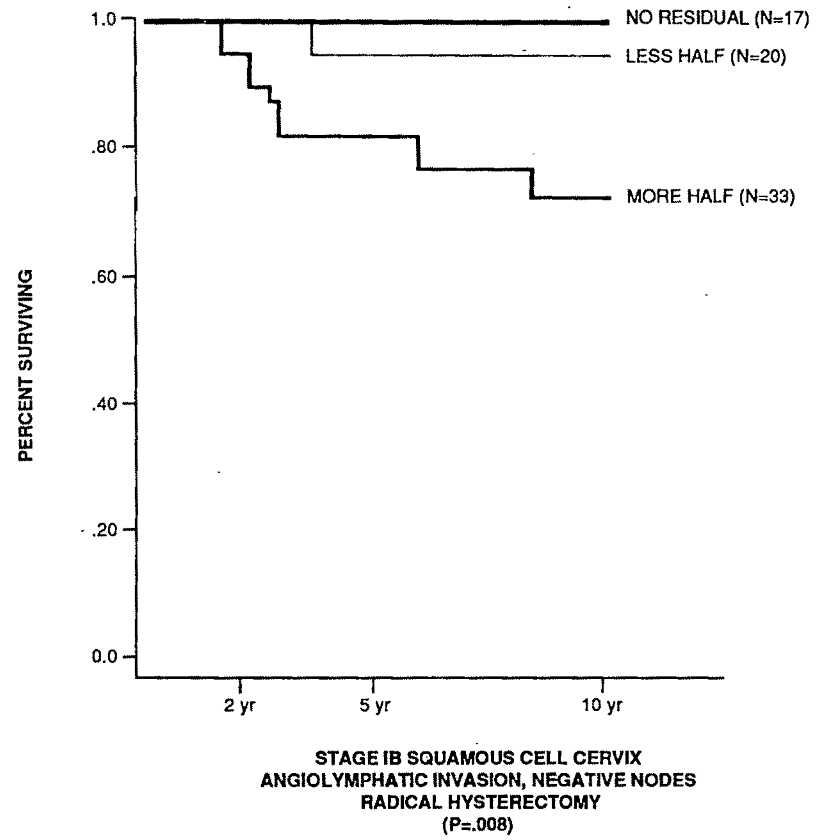

Fig. 8. Survival for patients undergoing radical hysterectomy with angiolymphatic invasion according to depth of cervical penetration, with negative lymph nodes.

tumors compared with 94% in well-differentiated or moderately differentiated lesions; these results are similar to ours. Chung et al.[15] also reported that patients with a poorly differentiated tumor had a higher incidence of recurrence and a lower 2-year survival.

Angiolymphatic invasion has been reported with variable results. Creasman et al.[3] reported that angiolymphatic invasion did not influence survival whereas Gauthier et al.[6] reported a decrease in survival from 92% to 83% when angiolymphatic invasion was present. Angiolymphatic invasion in the previously reported time period from our institution also influenced survival, although our recent survival of 88% is better than the 73% previously reported.[14] A previous report by White et al.[16] covering a 10-year time period from our institution reported no difference in survival. However, when a greater number of patients is analyzed in our present report, the survival for patients with angiolymphatic invasion decreases while the reported survival of 97% for patients without angiolymphatic invasion remains the same.

The lymph node status has been reported by all authors to significantly influence survival. Survival dropped to 60% in this report when all patients with positive lymph nodes were evaluated. The survival was also significantly influenced by the number of positive lymph nodes and decreased significantly when more than three nodes were involved. Survival also decreased when metastatic disease to regional lymph nodes was present bilaterally; however, all of these patients but one also had more than three positive lymph nodes. Thus these two factors oftentimes coexist.

The tumor size, lower uterine segment involvement, and depth of cervical penetration appear to significantly influence survival. Grimard et al.[7] reported that in stage IB disease the survival decreased from 90% to 50% when the lower uterine segment was involved. Gauthier et al.[6] evaluated risk groups and found the highest-risk group to have lesions >3 cm in size and deep cervical penetration. Underwood et al.[5] also found size and depth of invasion to significantly influence survival. Kishi et al.[8] evaluated the depth of invasion by determining the amount of fibromuscular stroma remaining at the paracervical margin. They reported an 8% mortality when 5 mm of thickness remained. The mortality increased to 26% when thickness was <3 mm and 57% when the margins were exposed. Creasman et al.[3] reported a 93% survival when only occult disease was present in the cervix; this rate is similar to that in our patients with no residual disease or <50% cervical penetration. The incidence of positive lymph nodes increases significantly with increasing depth of cervical invasion, and this factor was the major factor influencing survival in our Cox model.

Patients with stage IB squamous cell cancer of the cervix and poorly differentiated tumors, node metastases, deep cervical penetration, lower-segment involvement, or angiolymphatic invasion are at a higher risk for recurrence. As active chemotherapeutic agents are identified, these high-risk groups should be considered for adjuvant therapeutic trials.

Discussion

Dr. Christopher J. Jolles, Salt Lake City, Utah. The authors state that the purpose of their retrospective study is to define clinical and pathologic features that predict recurrence of cervical cancer and enable them to select patients for adjunctive postoperative therapy. It is hoped that most high-risk patients are identified before radical hysterectomy; however, the clinician may use the available data in the selection of patients for radiotherapy after surgical exploration.

A major contribution of this series is the authors' confirmation of the findings of Kishi et al.[1] that the fraction of cervical invasion is a critical determinant of survival. Indeed they state that the amount of cervical stromal invasion was a more important determinant of survival than tumor size and lymph node status, although significant correlation was found between these features. It makes some sense that the fraction of cervix involved with tumor is an important factor. As the tumor involves greater fractions of cervical stroma, it gains access to the larger lymphatic trunks, which insert on the periphery of the cervix and probably serve as metastatic conduits. Given two tumors of equal size, one occurring in a small, primiparous or atrophic cervix and another in a large, grandmultiparous cervix, one can accept that the likelihood of metastatic spread is different.

As a logical extension of this work, I would make the observation that the current generation of magnetic resonance scanners are often able to visualize cervical tumors in many anatomic planes and distinguish them from uninvolved cervical stroma. One could thereby determine an approximate fraction of cervical stromal invasion without surgery and potentially develop radiographic criteria that would help the clinician determine the optimal treatment modality for an individual with early cervical cancer.

Before we apply these data in the clinic, we must be assured that possible sources of bias are not present. It should be recognized that the fraction of cervical stroma invaded was frequently determined in the radical hysterectomy specimen after conization, an operation that presumably removes a significant portion of tumor and thereby factitiously decreases the observed extent of cervical invasion. I would ask the authors how the data would be altered if the preconization tumor thickness were used in patients who underwent conization?

It is concerning that, unlike in previous reports, the presence of nodal metastases was not the most important determinant of survival. In this series the status of lymph nodes was established surgically. I note that lymph node status was known in 261 patients, yet only 213 underwent radical hysterectomy. What were the findings and clinical outcomes of the 48 patients who underwent exploration but who did not undergo radical surgery? Why was surgery not completed? If we knew the percentage of stromal invasion present in these cases, would it strengthen the authors' assertion that percentage of stromal invasion is as important a survival determinant as nodal metastasis? It is stated in the manuscript that the addition of radiation for high-risk indications did not influence survival in this series, but this issue was not rigorously examined and remains an important question that merits further prospective study.

I was intrigued by an unusual aspect of the patients described. A "normal Papanicolaou smear" had been obtained within one year of diagnosis in almost half of the patients. It has been observed that in well-screened populations the fraction of patients with cervical cancer who had recently had a negative Papanicolaou smear has increased significantly over the past several years, yet this number seems rather excessive and represents a most important and concerning contribution of their study. Have these Papanicolaou smears been reviewed? In the authors' opinion does this reflect a true change in the behavior of the disease, or does it reflect remediable clinical error on the part of the cytopathologist or the gynecologist?

Dr. Howard W. Jones III, Nashville, Tennessee. This is an extensive review of the factors influencing prognosis in women with stage IB squamous cell carcinoma of the cervix. Their overall 5-year survival rate of 89% is excellent, and the 17% incidence of pelvic lymph node metastases in their series indicates that this is a representative sample of patients with stage IB disease. It is of interest that the survival rates reported here for patients treated from 1970 through 1985 are almost indentical to the results reported by Drs. Morley and Seski[1] for patients treated at the University of Michigan between the years 1945 and 1975. In that report adenocarcinoma of the cervix accounted for an increasing percentage of stage IB—from 3% during the first 10 years to 11.9% for the last 10-year period. This group also had a significantly worse prognosis, a 62% 5-year survival compared with 91% for the squamous cell lesions. Other authors also have noted a relative increase in the incidence of cervical adenocarcinoma, but most recent series[2] have shown no real difference in survival. You have restricted your report to squamous cell lesions, but I wonder if you have additional information concerning the patients with stage IB cervical adenocarcinoma?

Using the Cox statistical model, you found that the most significant prognostic characteristic was depth of cervical involvement by tumor. It is not clear to me exactly how this depth was measured or how those patients who had previously undergone cone biopsy were handled. In an excellent study Burghardt and his colleagues[3] from Graz, Austria, studied giant sections of 325 women treated surgically for cervical carcinoma. Using these sections, which included cross sections of the entire cervix and adjacent parametria, they were able to measure the area of the cervix and the area of the tumor. By this very exacting technique, they showed a 97.5% 5-year survival for women with <20% of the cervical area involved by tumor. This was statistically better than that of those women who had >20% involvement, in whom the survival rates were between 71% and 78%. It is somewhat surprising that in the authors' study cervical tumor invasion was a more significant indicator of prognosis than lymph node metastasis.

Finally, the authors said very little about their management protocol for women with stage IB cervical cancer. Did the type of therapy influence prognosis? What factors were used to select either radiation or radical surgery for their patients? How were patients with positive nodes managed?

While I congratulate the authors on this extensive work, I was disappointed not to find any new insights into the prognostic characteristics or management of women with stage IB squamous cell carcinoma of the cervix.

DR. HOPKINS (Closing). I thank Dr. Jolles and Dr. Jones for their discussions. In regard to some of the questions, in the patients that underwent exploration for radical hysterectomy but in whom the procedure was not completed, the survival in that group was approximately 50%. Most of the time the radical hysterectomy was not done because of extremely high-risk features, such as large matted lymph nodes or common iliac periartic lymph nodes being diseased.

One or two of the patients had disease extension beyond the cervix at the time of exploration. That was a feature that did significantly influence survival when we looked at it.

None of the cytologic smears were reviewed. Most of them were not available for review, and what we looked for was whether the patients had reported a normal Papanicolaou smear within a year. So these patients had all been to a gynecologist, had been screened, and had negative reports. I think that would be a separate study on the false-negative rate of cytologic testing.

This article picked up on the previous report by Dr. Morley and Dr. Seski. In that report they gave the survival through 1970. The period 1970 through 1975 was not used for survival analysis in that report, so we went to the next 15 years, from 1970 to 1985, and reported that survival. Those 5 years from 1970 to 1975 include patients that we used for this survival analysis; they had not been used before.

During the same time period, we previously reported on adenocarcinoma of the cervix. Survival in that group was approximately 60% for stage I.

As to the measurement and depth of the cervical penetration, that's a difficult measurement to get. In patients who have radiation, obviously that depth cannot be ascertained. We used radical hysterectomy specimens and the cone biopsy specimens. Most of the time we had the radical hysterectomy specimen to use, and we measured from the squamous columnar junction over the site where the tumor began. We measured the entire cervix. We did not report as precisely as 20% but designated them as no tumor left in the cervix, <50% left, and >50% left.

The depth of invasion was a significant predictor of lymph node metastases, and that's why it became so important in the Cox model. Patients with deep penetration were more likely to die of the disease. The chances of having lymph node metastases were far greater for those patients where the depth was >50%.

We did look at the therapy but did not present our findings. The survival was equal in the patients who had radical surgery and those who had radiation therapy. So those data are similar to the findings previously reported by Dr. Morley.

Hysterosalpingography with color Doppler ultrasonography

Albert J. Peters, DO, and Carolyn B. Coulam, MD
Indianapolis, Indiana

To assess the accuracy of the diagnosis of tubal occlusion with the use of color Doppler flow ultrasonography and hysterosalpingography, 129 infertile women were studied. All 129 women had the procedure performed with an ATL Ultramark 9 (Advanced Technology Laboratories, Bothel, Wash.) color Doppler ultrasonography machine. Eighty-five of the 129 women also had an additional study including x-ray hysterosalpingography and/or chromopertubation. Of these 85 women, 58 had pelviscopic examination with chromopertubation. The frequency of diagnosis of tubal occlusion was compared among the three methods. When results of ultrasonography-hysterosalpingography were compared with those of x-ray hysterosalpingography and/or chromopertubation, 69 of 85 (81%) studies showed agreement, and 50 of 58 (86%) ultrasonography-hysterosalpingography findings agreed with observations at chromopertubation. The frequency of comparable findings between x-ray hysterosalpingography and chromopertubation is 75%. These data suggest that ultrasonography-hysterosalpingography is at least as accurate as x-ray hysterosalpingography in diagnosing tubal occlusion. In addition, ultrasonography-hysterosalpingography is safer and more cost-effective than x-ray hysterosalpingography and chromopertubation. (AM J OBSTET GYNECOL 1991;164:1530-4.)

Key words: Ultrasonography, hysterosalpingography, x-ray hysterosalpingography, tubal occlusion, chromopertubation

Tubal factors account for approximately 25% of the causes of infertility among three million couples in the United States.[1, 2] The diagnosis of tubal factor traditionally has been made by insufflating the fallopian tubes. In 1914, Rubin[3] described the use of the first attempt to assess tubal patency. Since that time a variety of techniques to demonstrate tubal patency have been used, including x-ray hysterosalpingography, chromopertubation at the time of laparoscopy, and radionuclide hysterosalpingography.[4] The most frequently used procedures to evaluate tubal patency currently are x-ray hysterosalpingography and chromopertubation. These procedures require the use of radiopaque dye, radiation, general anesthesia, and an operation. Ultrasonographic color Doppler flow does not require any of these risks. Therefore the accuracy of ultrasonographic color Doppler flow used to perform hysterosalpingography was studied.

Material and methods

One hundred twenty-nine women undergoing evaluation for infertility were studied for the presence or absence of tubal patency with ultrasonography-hysterosalpingography. The procedure was performed by instilling 5 to 50 ml of sterile saline solution transcervically through an H-S catheter (Ackrad Laboratories, Inc., Cranford, N.J.) into the endometrial cavity. Direction and flow into and out of the fallopian tubes were observed with color Doppler flow ultrasonography on an ATL Ultramark 9 (Advanced Technology Laboratories, Bothel, Wash.). Approximately half of the patients underwent Doppler scans transabdominally and one half transvaginally. When no fluid was observed to pass through the fallopian tubes or when no fluid was seen to enter the peritoneal cavity, tubal occlusion was diagnosed. The presence or absence of tubal occlusion diagnosed by ultrasonography-hysterosalpingography was compared with the results from x-ray hysterosalpingography and/or chromopertubation in the same woman. Of the 129 women who had ultrasonography-hysterosalpingography performed, 85 also had x-ray hysterosalpingography and/or chromopertubation procedures. Fifty-eight of these 85 women underwent pelviscopic examination with chromopertubation. In the remaining 71 patients, evaluation was not yet completed and laparoscopy had not been performed. The results of ultrasonography-hysterosalpingography were compared with the findings of x-ray hysterosalpingography and chromopertubation. In most cases x-ray hysterosalpingography had been performed before the patient's presentation to the Center for Reproduction and Transplantation Immunology. Two patients required

a sedative before the procedure. None required antimicrobial treatment. No post-procedure infections occurred.

Results

Table I summarizes the findings of ultrasonography-hysterosalpingography from 129 women undergoing infertility evaluation. Bilateral tubal patency was diagnosed in 66%, unilateral patency in 16%, and bilateral tubal occlusion in 18%.

When the results of ultrasonography-hysterosalpingography were compared with those of x-ray hysterosalpingography and/or chromopertubation, 69 of 85 (81%) studies showed agreement, that is, patency or occlusion of the fallopian tube (Table II). Fifty of 58 (86%) ultrasonography-hysterosalpingography findings agreed with observations at chromopertubation at the time of laparoscopy (Table I). When ultrasonography-hysterosalpingography findings of each tube were compared with those of chromopertubation at the time of pelviscopic examination, 81% sensitivity and 94% specificity were calculated by the use of χ^2 analysis. The false-negative and false-positive rates for ultrasonography-hysterosalpingography in this group of patients were 19% and 6%, respectively. There were eight instances (14%) in which the ultrasonography-hysterosalpingography findings did not correlate with those of chromopertubation. In each of these instances unilateral tubal occlusion was diagnosed by one of the methods. Two studies revealed bilateral tubal patency on ultrasonography-hysterosalpingography whereas chromopertubation showed unilateral patency. Two other studies showed unilateral tubal patency with ultrasonography-hysterosalpingography, one of which revealed bilateral tubal patency and the other bilateral tubal occlusion at the time of laparoscopy with chromopertubation (Table II).

When x-ray hysterosalpingography was compared to chromopertubation in this group of patients, 22 of 31 (71%) studies correlated at the time of operation. The sensitivity and specificity of x-ray hysterosalpingography in this study were 65% and 82%, respectively. The false-negative and false-positive rates of x-ray hysterosalpingography in this group of patients were 45% and 18%, respectively. This difference in correlation between ultrasonography-hysterosalpingography and chromopertubation (86%) and x-ray hysterosalpingography (71%) is not significant ($p = 0.7$).

Comment

Presented in this study is a new technique to assess fallopian tube patency. When this technique was compared with the more traditional techniques of assessing tubal patency, it was found to correlate well with the diagnosis of tubal occlusion. The frequency of tubal occlusion diagnosed by ultrasonography-hysterosalpingography correlated with x-ray hysterosalpingography and/or chromopertubation 81% of the time. When the results of ultrasonography-hysterosalpingography are compared with those of chromopertubation alone, a correlation existed 86% of the time. The diagnosis of tubal occlusion made with x-ray hysterosalpingography correlated with chromopertubation 71% of the time (Table III).[5-7] This value was similar to other comparisons in the literature.[5, 6] If chromopertubation is considered the gold standard for diagnosing tubal occlusion, ultrasonography-hysterosalpingography findings are at least as accurate as or more accurate than x-ray hysterosalpingography results in demonstrating tubal occlusion.

Table III. Comparison of x-ray hysterosalpingography to chromopertubation to assess tubal patency

Series	No. of procedures		Correlation
	Total	Correlation	
Keirse and Vanderwellen[5]	50	38	76%
Servy and Tzingounis[6]	97	74	77%
This study	31	22	71%
TOTAL	178		75%

In all instances in which the ultrasonography-hysterosalpingography findings did not correlate with the chromopertubation results, discrepancies involved a diagnosis of unilateral patency. We are now recommending repeating ultrasonography-hysterosalpingography when unilateral tubal occlusion is observed before proceeding with laparoscopy. The results of this study will help clarify the meaningfulness of the finding of unilateral patency at the time of hysterosalpingography, as well as define the frequency of unilateral tubal occlusion in infertile women.

In addition to the enhanced efficacy of ultrasonography-hysterosalpingography in diagnosing tubal occlusion, other advantages exist. No anesthetics, antimicrobials, or contrast dyes are necessary. The only agent used is sterile saline solution; therefore the risk of adverse reactions is minimized. There is also no exposure to radiation. The procedure is performed in the office setting, which makes it more convenient for both patient and physician. Costs are less. At our institution the cost to the patient for x-ray hysterosalpingography is approximately $400. The cost of ultrasonography-hysterosalpingography is approximately $250.

Difficulty in making a diagnosis of tubal occlusion arises in those patients with dilated hydrosalpinges because flow through the dilated fallopian tube may simulate spillage on the Doppler ultrasonography screen. In addition, tubal architecture is not demonstrated with Doppler flow hysterosalpingography as it is with x-ray hysterosalpingography. However, a recent study has shown this information is not useful in preoperative salpingoplasty procedures.[8]

Ultrasonography-hysterosalpingography is a new technique to assess fallopian tube patency that can easily be performed in an office setting with minimal discomfort, low cost, and high accuracy when compared to the more traditional techniques.

In conclusion, this study represents results of the use of color Doppler flow ultrasonography to assess fallopian tube patency in the infertile patient. The procedure is as good as x-ray hysterosalpingography in evaluating tubal patency when both techniques are compared to chromopertubation at the time of laparoscopy. Other advantages such as lower cost, convenience, lack of exposure to radiation, no anesthetics, and no operative complications are attractive. Disadvantages include possible false-positive results of patency when the patient with a hydrosalpinx is evaluated. As more patients are evaluated with this technique, its place in the investigation of the infertile couples will be established.

Discussion

Dr. John F. Randolph, Ann Arbor, Michigan. The search for an easier, cheaper, and more convenient method for assessing the anatomy of the upper female genital tract in the evaluation of the infertile couple has not produced a more promising technique than the one described by the authors. With the increasing availability of real-time ultrasonography in the offices of physicians treating couples with infertility, the availability of color Doppler ultrasonography offers the possibility of an immediate assessment of upper genital tract anatomy on presentation of the patient. This new technique takes advantage of the technologic evolution of an idea initially investigated in the early 1980s.

I had the privilege of conducting a similar study[1] with an earlier generation of ultrasonographic equipment and encountered a number of difficulties pertinent to the study under discussion. In that study 61 women underwent real-time transabdominal pelvic ultrasonography during the instillation of saline solution into the uterus after being anesthetized in preparation for surgical evaluation of the pelvis. With the equipment available at that time patency of the fallopian tubes could easily be demonstrated by the accumulation of fluid in the cul-de-sac, but flow through the tubes was difficult to determine. Therefore the patency or occlusion of an individual fallopian tube was often undetermined. Color Doppler ultrasonography presents a more sensitive measure of flow through the tubes and therefore makes the individual tubal patency more measurable.

It also became clear in our earlier study that assessment of a new technique required a careful comparison with an established gold standard to determine sensitivity and specificity. By use of such measurements the inherent properties of a test or technique can be measured independently of a particular patient population and allow meaningful evaluations of the technique in various clinical studies.

The authors presented data to support the hypothesis that ultrasonography-hysterosalpingography was at least as accurate as x-ray hysterosalpingography in assessing tubal patency. Unfortunately, the data as presented are incomplete and therefore do not allow an accurate analysis of the study. It is not obvious from the data how many patients had undergone x-ray hysterosalpingography or how many patients had undergone all three procedures. The ideal comparison of ultrasonography-hysterosalpingography to x-ray hysterosalpingography with chromopertubation at the time of operation as the gold standard should be made in patients who had all three procedures performed. If the assessment is limited to patients having chromopertubation only as compared to ultrasonography-hysterosalpingography, then values for sensitivity and specificity can be calculated. However, side-specific patency is not indicated and becomes a critical omission for the determination of the properties of the new technique.

In particular, five patients were listed as demonstrating unilateral patency with both techniques. Without an indication of which tube was patent with each technique it is impossible to determine if the tests were in complete agreement or complete disagreement for any individual patient. On the basis of the possible extremes, the calculated sensitivity for ultrasonography-hysterosalpingography versus chromopertubation ranges from 89% to 95% and the specificity from 74% to 88%.

Additionally, the authors concluded that ultrasonography-hysterosalpingography is safer and more cost-effective than x-ray hysterosalpingography or chromopertubation. With a generally accepted infectious morbidity rate of about 1% after x-ray hysterosalpingography, it is premature to conclude a lower rate of infectious morbidity with only 129 women studied, although the risks of ionizing radiation, iodinated contrast materials, general anesthesia, and operative endoscopy are avoided. Moreover, without cost figures for comparison and with the significant expense of color Doppler ultrasonographic equipment, it is not possible to establish definite cost savings.

I beseech the authors to please provide us with more complete data with which to evaluate this exciting new advance. Intuition urges us to support their conclusions, but the data do not.

1. Randolph JR Jr, Ying YK, Maier DB, Schmidt CL, Riddick DH. Comparison of real-time ultrasonography, hysterosalpingography, and laparoscopy/hysteroscopy in the evaluation of uterine abnormalities and tubal patency. Fertil Steril 1986;46:828-32.

Dr. Rudy E. Sabbagha, Chicago, Illinois. This article examines the accuracy of diagnosing fallopian tube patency by color Doppler ultrasonography. In the study only 58 of 129 infertile women were selected for examination by both ultrasonography-ultrahysterosalpingography and laparoscopic chromopertubation. However, the selection criteria were not described and the outcomes for the remaining 71 patients were not detailed. Similarly the selection criteria for ultrasonographic and x-ray imaging were not presented.

In the study the correlation between ultrasonography and laparoscopy (86%) appears similar to that between x-ray hysterosalpingography and chromopertubation (71%). However, these differences were not compared statistically and the results fall in the realm of impressions. A number of advantages pertaining to color Doppler ultrasonography also were listed, including lack of radiation, possible decrease in the use of pelviscopic examination with the patient under general anesthesia, and cost-effectiveness. However, the latter 2 statements remain unconfirmed.

Specifically, pelviscopic examination provides the gynecologist with information in addition to tubal patency, including presence of uterine myomas or anomalies, tubal dilation or adhesions, or both, and endometriosis. Thus without a blinded prospective study it may not be possible to conclude that ultrasonography will translate into a decrease in the use of pelviscopic examination with the patient under general anesthesia.

As to cost-effectiveness of ultrasonography, the authors did not supply us with data comparing the cost of ultrasonography to x-ray hysterosalpingography. In such comparisons one has to consider that each ultrasonographic machine with color Doppler capability comes with a price tag of approximately $180,000. When indirect cost is factored in with equipment depreciation, as well as with physician and allied health ultrasonographer time, the cost may not be different from that of x-ray hysterosalpingography.

Finally, although the authors quoted a reference that dismisses any benefit to the evaluation of tubal architecture and dilation by x-ray hysterosalpingography, many gynecologists find that the overall information gathered by this x-ray method is important. This includes identification of uterine anomalies and/or distortion of the uterine cavity by submucous or intramural myomas. Certainly, the uterus, including the uterine cavity, also can be evaluated by vaginal ultrasonography. However, such evaluation is likely to drive the cost of the procedure upward.

The authors have shown an interesting application of new technology—color Doppler ultrasonography. However, additional data are necessary to define its precise role and its possible advantages.

Dr. L. Russell Malinak, Houston, Texas. I would like to ask the authors how many patients were nulligravid and how many were parous. It seems that a 1 ml balloon in the uterus of a nulligravid woman might be associated with pain and consequent spasm of the uterus and fallopian tubes. How painful was the procedure?

Is there an advantage in using Doppler equipment over a standard ultrasonography machine, and can you visualize peritubal adhesions, as in hysterosalpingography?

Dr. Peters (Closing). Thank you for your thoughtful comments and your questions. We did look at sensitivity and specificity and found an 89% sensitivity along with a 90% specificity.

Regarding Dr. Sabbagha's question concerning patient selection, these patients presented to Dr. Coulam's practice with the complaint of infertility and they had fulfilled the standard criteria of infertility. They had already undergone one form of assessment of tubal patency.

Dr. Sabbagha also brought out the point of possibly trying to replace pelviscopic examination. The intent was not to replace pelviscopy, just as x-ray hysterosalpingography does not replace pelviscopy, but simply to give us another mode of studying the fallopian tube. Indeed, if patency can be assessed equally well with ultrasonographic hysterosalpingography, it may possibly give x-ray hysterosalpingography some competition.

However, we did not intend to omit pelviscopic examination because, as suggested, many things can be found at the time of pelviscopic examination that could be critical to the infertile patient.

As to the cost issue, yes, indeed, Doppler ultrasonography machines are very expensive. I would suppose and hope that with time the cost of those machines will decrease, as with most new technologies.

As far as cost per procedure, the cost of this particular procedure is approximately $165 in our institution, which is the cost of the scan. In our institution the cost of x-ray hysterosalpingography is close to $300. So there is a significant cost saving there.

As to Dr. Malinak's question, I'm sorry, I don't know the exact percentage of patients that were primigravid or multigravid. However, I did not have difficulty maintaining the balloon within the uterine cavity. As I stated in the advantages, most of the patients claimed that they had less discomfort than with x-ray hysterosalpingography.

We cannot provide, at least with our skill, at this point an adequate assessment of peritubal disease.

Dr. Randolph brought up the point of sensitivity and specificity that I did address.

I was not referring to safety in the sense that the radiation was so great that it would harm the patient. I was referring to the allergic types of reactions that some patients encounter with the contrast dyes, which are eliminated simply because we're using saline solution.

Comparison of associated high-risk factors and perinatal outcome between symmetric and asymmetric fetal intrauterine growth retardation

Chin-Chu Lin, MD, Shyr-Jou Su, MD, and L. Philip River, BA
Chicago, Illinois

This study compares associated high-risk factors and perinatal outcome between 273 symmetric and 445 asymmetric infants with intrauterine growth retardation. No differences were seen in 17 obstetric, medical, and environmental-behavioral high-risk factors between symmetric and asymmetric intrauterine growth retardation. In preeclampsia, the incidence of symmetric intrauterine growth retardation is higher than that of asymmetric intrauterine growth retardation. The timing of the interaction between the high-risk factor and the stage of gestation is more important than the specific high-risk factor in determining whether symmetric or asymmetric intrauterine growth retardation is produced. On comparison of perinatal outcome between the two groups, we concluded: (1) that the onset of symmetric intrauterine growth retardation occurs much earlier in the course of pregnancy than does asymmetric intrauterine growth retardation, (2) that more symmetric than asymmetric pregnancies with intrauterine growth retardation result in preterm delivery, (3) that the neonatal morbidity rate for symmetric intrauterine growth retardation is higher than that for asymmetric intrauterine growth retardation, and (4) that term symmetric infants with intrauterine growth retardation tend to have a lower mean birth weight and a higher incidence of small placentas than term infants with asymmetric intrauterine growth retardation. (AM J OBSTET GYNECOL 1991;164:1535-42.)

Key words: Symmetric IUGR, asymmetric IUGR, associated high-risk factors, perinatal outcome

Intrauterine growth retardation (IUGR) is recognized as an important cause of low birth weight, second only to the problem of preterm birth.[1] The IUGR infant is associated with multiple causative factors[2, 3] and with high levels of perinatal mortality and morbidity.[4-7] Two types of IUGR infants have been identified clinically: symmetric and asymmetric.[3, 6, 7] The purpose of this study was to compare associated high-risk factors and perinatal outcome between symmetric and asymmetric IUGR infants.

Patients and methods

Between July 1979 and December 1985, 718 IUGR infants among a total of 22,616 infants were delivered at the Chicago Lying-In Hospital, The University of Chicago. During the study period, all patients with high-risk factors were enrolled prenatally in either the Obstetric High-Risk Clinic or the Medical High-Risk Clinic. Historic high-risk factors were recorded during the initial visit, and high-risk factors that developed during gestation were identified in subsequent clinical visits. Clinical data for all high-risk patients during pregnancy were entered into the University of Chicago OB-File computer system whenever a high-risk factor was identified. High-risk patients then had close follow-up, with intervals of 1 to 2 weeks at our high-risk clinics. Clinical data of low-risk obstetric patients during pregnancy were not entered into the computer system. However, clinical data of labor and delivery and newborn data for both high- and low-risk patients who were delivered at our institution were entered into the computer system. During the study period, 3788 patients had prenatal care at our high-risk clinics.

Clinically suspected IUGR cases, such as those with retarded uterine fundal height, were further evaluated by serial ultrasonographic measurements to establish the diagnosis of suspected IUGR. Multiple static axial and longitudinal images of the fetus and uterus were taken during each ultrasonographic examination. Each examination included fetal measurements such as biparietal diameter, head circumference, abdominal circumference, femur length, calculation of head circumference/abdominal circumference ratio, and estimated fetal weight. Each patient also was screened for gross fetal anomalies and quantitative amniotic fluid volume.

Table I. Comparison of incidences of various high-risk factors between symmetric and asymmetric IUGR*

High-risk factor	*Symmetric*	*Asymmetric*	χ^2 *Test*
Total cases	273	445	
Demographic-behavioral risk factor			
Primigravid	64 (23.4%)	100 (22.4%)	p = NS†
Age <17 yr	24 (8.8%)	26 (5.8%)	p = NS
Age >35 yr	8 (2.9%)	12 (2.7%)	p = NS
Smoking	77 (28.2%)	136 (30.6%)	p = NS
Alcohol	24 (8.8%)	37 (8.3%)	p = NS
Drug abuse	28 (10.3%)	33 (7.4%)	p = NS
Obstetric risk factor			
Preeclampsia	52 (19.0%)	55 (12.4%)	$p < 0.025$
Twin gestation	24 (8.8%)	36 (8.1%)	p = NS
Poor obstetric history	39 (14.3%)	44 (9.9%)	p = NS
Poor weight gain	40 (14.7%)	70 (15.7%)	p = NS
Antepartum hemorrhage	11 (4.0%)	15 (3.4%)	p = NS
Medical risks in current pregnancy:			
Chronic hypertension	25 (9.2%)	28 (6.3%)	p = NS
Anemia (hemoglobin <10 gm/dl)	44 (16.1%)	82 (18.4%)	p = NS
Urinary tract infection (symptomatic)	14 (5.1%)	36 (8.1%)	p = NS
Asthma	11	14	
Hemoglobinopathy	8	17	
Cardiac disease	5	6	
Diabetes mellitus	1	12	

*Each case of IUGR may have one or more high-risk factors.

†Power of statistics for 13 items with p = NS. We had a 7% chance of detecting a 20% difference in the groups.

A fetus with two abnormal results among the three parameters, such as abdominal circumference of <10th percentile, with a head circumference/abdominal circumference ratio of >2 SD above the mean, (e.g., 1.21 at 34 weeks, 1.05 at 40 weeks) or an estimated fetal weight <10th percentile was diagnosed as having suspected IUGR. Ultrasonographic evaluation, however, was not performed routinely for all of our obstetric patients, particularly during the first half of the study period, 1979 to 1982. Prenatally suspected IUGR cases were subjected to a weekly high-risk clinic visit and a nonstress test. A nonreactive nonstress test was followed by a contraction stress test,[8] a biophysical profile scoring evaluation,[9] or both. Antenatally suspected IUGR pregnancies were terminated at 38 weeks of gestation after documentation of fetal lung maturity. Earlier termination was carried out either for fetal indications or because of maternal deterioration, consistent with our management protocol.[10]

During labor and delivery, various signs of fetal distress, including abnormal fetal heart rate patterns, meconium-stained amniotic fluid, and fetal acidosis, were intensively monitored. At the time of delivery all IUGR infants were evaluated by two pediatricians. All of the preterm IUGR infants in the study series received neonatal care at The University of Chicago's intensive care nursery. After the infant was discharged from the intensive care nursery, the medical record of each preterm IUGR neonate was carefully reviewed and various neonatal morbidities such as respiratory distress syndrome, neonatal infection, neonatal acidosis, hypoglycemia, and hyperbilirubinemia were identified.

At the conclusion of data collection, all 718 IUGR infants were assigned to one of two groups, symmetric or asymmetric IUGR. The symmetric IUGR group was defined as <10th percentile for both body weight and head circumference for the gestational age at birth. The asymmetric IUGR group was defined as a birth weight of <10th percentile but head circumference of >10th percentile for gestational age, on the basis of our own fetal growth curve, which has been in existence since 1983.[3] Preterm IUGR was defined as <10th percentile for birth weight with a gestational age of <37 weeks.

For a comparison of associated high-risk factors, 18 factors (including seven medical complications, five obstetric factors, and six environmental-behavioral factors) were compared between the two groups. Fourteen factors were compared statistically by the χ^2 test for their incidence in each group. Four other factors were not analyzed because of the small number of cases in each category. Further analysis was performed for the 57 IUGR infants whose mothers developed preeclampsia; all of these cases had at least 4 weeks of prenatal care before delivery.

Several parameters of perinatal outcome were compared between symmetric and asymmetric IUGR infants by means of either the t test or the χ^2 test for statistical analysis.

Results

Associated high-risk factors. The overall incidence of IUGR during the study period was 3.2% (718 cases of IUGR per 22,616 total births). Among the 718 IUGR infants, 273 (38%) were symmetric and 445 (62%) were asymmetric IUGR according to the criteria mentioned previously. Approximately 80% of symmetric IUGR (217/273) and 70% of asymmetric IUGR (312/445) had one or more identifiable high-risk factors.

A comparative analysis of the 18 associated risk factors is shown in Table I. The incidence of each of the following risk factors was not statistically different between symmetric and asymmetric IUGR: chronic hypertension, anemia, symptomatic urinary tract infection, twin gestation, poor obstetric history, poor weight gain, antepartum hemorrhage, maternal age <17 years, smoking, use of alcohol, and drug abuse. For those risk factors with a small number of cases in each category, such as asthma, hemoglobinopathy, cardiac disease, diabetes mellitus, and maternal age >35 years, there was no difference in the incidence of symmetric and asymmetric IUGR. Preeclampsia was the only high-risk factor that exhibited a higher incidence of symmetric than asymmetric IUGR (19% vs 12%, $p < 0.025$).

Table II compares symmetric and asymmetric IUGR infants whose mothers had preeclampsia before delivery. The mean gastational age at the diagnosis of IUGR, the mean gestational age at delivery, and the mean birth weight all were significantly lower in the symmetric IUGR group when compared with the asymmetric IUGR group. Most symmetric IUGR infants were delivered of women with either early onset of moderate to severe preeclampsia or chronic hypertension with superimposed preeclampsia.

One symmetric and 12 asymmetric IUGR infants were born to diabetic mothers. Seven of the 12 asymmetric IUGR infants were the products of mothers with juvenile diabetes (three with class C, three with class D, and one with class F diabetes).

Antenatal diagnosis of IUGR. Approximately one third of the IUGR cases in the study were identified clinically and confirmed by ultrasonography during pregnancy in both groups (93 cases or 34.0% in the symmetric group and 134 cases or 30.1% in the asymmetric group, p = NS). Among IUGR fetuses diagnosed antenatally, the difference in the timing of clinical detection between symmetric and asymmetric IUGR was quite striking: before 32 weeks, 23% (21 cases) symmetric versus 2% (3 cases) asymmetric ($p < 0.001$, χ^2 test); at 34 weeks, 46% (43 cases) symmetric versus 14% (19 cases) asymmetric ($p < 0.001$, χ^2 test); and at 36 weeks, 82% (76 cases) symmetric versus 64% (86 cases) asymmetric ($p < 0.01$, χ^2 test). Fig. 1 illustrates cumulative curves of the incidences of clinical detection of the two types of IUGR according to gestational age.

Preterm delivery, birth weight, and placental weight. As shown in Table III, the incidence of preterm delivery was higher for symmetric than for asymmetric IUGR (32.6% vs 12.4%, $p < 0.001$).

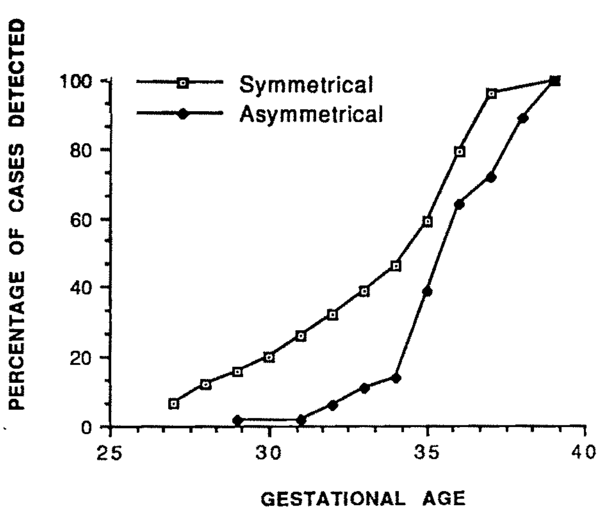

Fig. 1. Cumulative curves of incidences at time of clinical detection for symmetric and asymmetric IUGR according to weeks of gestation (see text for details).

Table II. Comparison between symmetric and asymmetric IUGR associated with maternal preeclampsia*

	Symmetric	*Asymmetric*	*t Test*
Total No. of cases	31	26	
Gestational week IUGR Diagnosed	29.5 ± 2.0	34.1 ± 1.5	$p < 0.001$
Gestational week at delivery	32.7 ± 3.1	36.7 ± 2.2	$p < 0.001$
Interval between diagnosis and delivery (wk)	3.2 ± 2.8	2.6 ± 2.2	p = NS
Birth weight (gm)	1300 ± 418	2050 ± 338	$p < 0.001$

*All patients had at least 4 weeks of prenatal care before delivery. All data expressed as mean ± SD.

Fig. 2 shows the mean birth weight according to gestational week for both symmetric and asymmetric preterm IUGR infants. For the purpose of comparison, a control curve of the mean birth weight by gestational week on the basis of a total of 3216 preterm non-IUGR infants delivered prematurely at out institution during the study period, ranging from 28 to 36 weeks, also is illustrated. As expected, the mean weight curves for both symmetric and asymmetric IUGR infants are far below the control curve. It is of interest to note that the mean weight curve for symmetric IUGR runs below that of asymmetric IUGR at each gestational week before 37 weeks.

Of those IUGR infants who were delivered at term (≥37 weeks' gestation), the mean birth weight of symmetric IUGR infants was significantly lower than that of asymmetric IUGR infants (2167 ± 260 vs 2385 ± 105 gm, $p < 0.001$ by t test). The incidence of small placenta at term gestation (defined as a placental weight of <400 gm) was significantly higher in symmetric than

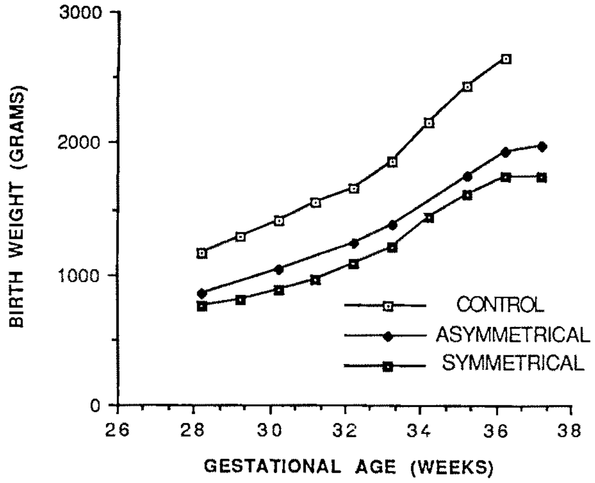

Fig. 2. Mean body weight by weeks of gestation for preterm symmetric and asymmetric IUGR. Control curve is obtained from mean birth weight data for our 3216 preterm appropriate-for-gestational-age population during the study period. Mean birth weight data were calculated week by week according to gestational age between 28 and 36 weeks.

Table III. Perinatal events and fetal outcome

	Symmetric	*Asymmetric*	χ^2 *Test*
Total No. of cases	273	445	
Preterm birth	89 (32.6%)	55 (12.4%)	$p < 0.001$
Total intrapartum fetal distress*	117 (42.9%)	153 (34.4%)	p = NS
Abnormal FHR with MSAF	54 (19.8%)	69 (15.5%)	p = NS
Abnormal FHR with pH <7.20	36 (13.1%)	23 (5.2%)	$p < 0.05$
Cesarean section	55 (20.1%)	71 (16.0%)	p = NS
Apgar score ≤6			
1 min	87 (31.9%)	91 (20.4%)	$p < 0.01$
5 min	43 (15.8%)	35 (7.9%)	$p < 0.05$
Neonatal death	24 (8.8%)	8 (1.8%)	$p < 0.001$
Fetal anomalies†	16 (5.9%)	13 (2.9%)	p = NS

FHR, Fetal heart rate; *MSAF*, meconium-stained amniotic fluid.

*Intrapartum fetal distress. All cases had abnormal fetal heart rate patterns, some of them combined with meconium-stained amniotic fluid and fetal acidosis.

†Two cases of chromosomal abnormalities and one case of cytomegalovirus in the symmetric group and three cases of chromosomal abnormalities in the asymmetric group.

in asymmetric IUGR (37.5% vs 12.6%, $p < 0.001$ by χ^2 test).

Perinatal events and fetal outcome. As shown in Table III, fetal outcome for symmetric IUGR was much worse than for asymmetric IUGR infants. There was a higher incidence of preterm delivery, depressed Apgar scores at both 1 and 5 minutes, fetal acidosis, and neonatal death. However, the incidences of total intrapartum fetal distress, cesarean delivery, and gross fetal anomalies were not significantly different between the two groups.

Neonatal morbidity among preterm IUGR infants. Neonatal morbidity among the 89 preterm symmetric IUGR and the 55 preterm asymmetric IUGR infants is compared in Table IV. The incidences of low 5-minute Apgar score, respiratory distress syndrome, neonatal infection, and neonatal acidosis were higher for symmetric than for asymmetric preterm IUGR infants. There were no significant differences between the two groups in the incidence of hyperbilirubinemia, hypoglycemia, or low 1-minute Apgar score.

Comment

An IUGR infant is commonly defined as one weighing <10th percentile in birth weight for gestational age.[11] However, because there is no standard population from which to derive these percentiles, the birth weights that serve as the cutoff point by various published studies may differ as much as several hundred grams at any gestational week during the third trimester.[12] This variability may result from population differences in sex, or race and from different geographic areas studied, as well as differences in study methods. In this study we used a fetal growth curve (constructed by Lowensohn and based on total live births between 1978 and 1982 at our institution) to define IUGR if the birth weight fell below the 10th percentile line for each gestational week (Fig. 3).[3] A comparison of the 10th percentile line of two different fetal growth curves shows a close similarity between the Chicago and the Colorado curve.[11] The 10th percentile growth curve from the state of California,[13] however, suggests that their newborns at the cutoff point for IUGR between 26 and 36 weeks of gestation are heavier than ours. When we used the Chicago curve to study a total of 7177 deliveries at our institution between January 1979 and May 1981, there were 426 IUGR newborn infants, an incidence of 5.9%.[3] In this study the incidence of IUGR was 3.2% according to the same study method in the same institution but during a different study period. The reason for this difference in the incidence of IUGR during two time periods is not well understood.

Among 718 IUGR infants in this study series, 189 (26.3%) were not associated with any high-risk factors. We believe that many of them, particularly those with symmetric IUGR, may belong to the group of so-called "constitutionally small" babies. On the basis of a four times increased risk of stillbirth, Myers and Ferguson[14] studied a population in the state of Illinois and argued that the 3rd percentile should be used to define IUGR in preterm gestations before 31 weeks, whereas the 15th to 17th percentile should be used to define IUGR

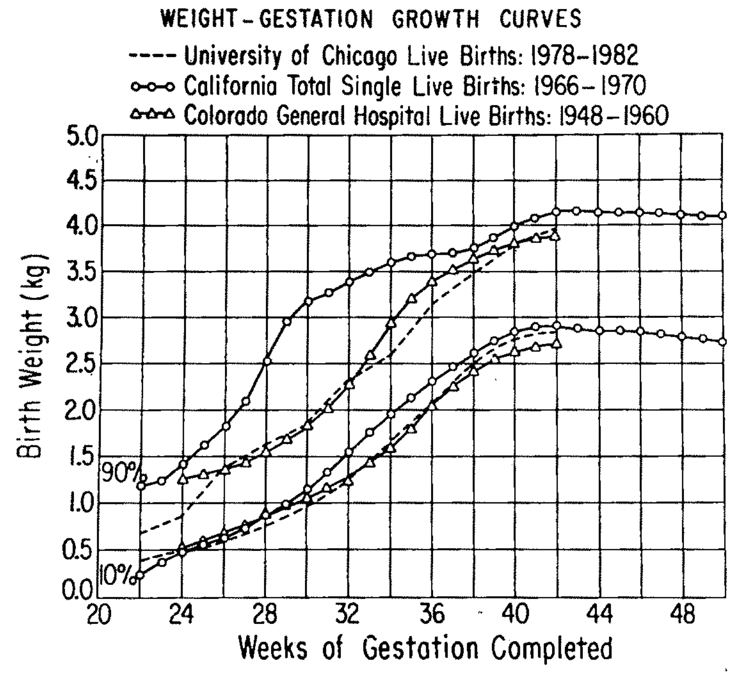

Fig. 3. Weight–gestational age fetal growth curves of the University of Chicago, state of California, and Colorado General Hospital. Both 10th and 90th percentile lines are shown. Note Chicago and Colorado 10th percentile lines are in close agreement. (Courtesy of R.I. Lowensohn. From Lin C-C, Evans MI, eds. Intrauterine Growth Retardation: Pathophysiology and Clinical Management. New York: McGraw-Hill, 1984:40. Reproduced with permission from McGraw-Hill, Inc.)

in those pregnancies approaching term gestation. In view of the heterogeneity of the various causes of IUGR, there are some inevitable limitations to using the 10th percentile of birth weight as the sole criterion for diagnosing IUGR.

Among six infants with chromosomal abnormalities and congenital viral infection, three cases were in the symmetric IUGR group and the other three cases were in the asymmetric IUGR group. In all three cases in the asymmetric group, the head circumference measurements were between the 10th and 25th percentiles. Using a definition of less than the 25th instead of the 10th percentile for head circumference to define symmetric IUGR would place all of these cases in the symmetric group. This idea is consistent with the findings of Sabbagha,[15] who reported an incidence of IUGR infants of >50% in cases associated with a small biparietal diameter (<25th percentile) in early pregnancy. However, if adopting a definition of <25th percentile for head circumference to differentiate symmetric from asymmetric IUGR would lead to an unrealistically high incidence of symmetric IUGR in our study population. If a criterion of <10th percentile for head circumference is used to define symmetric IUGR, the 38% incidence of symmetric IUGR in this study series is already somewhat higher than the 20% to 25% incidence of symmetric IUGR cited in the literature.[2, 3, 16] Obviously, this dilemma of whether to use the 10th or the 25th percentile for head circumference to define symmetric IUGR is difficult to resolve.

Table IV. Neonatal morbidity among preterm IUGR infants

	Symmetric	*Asymmetric*	χ^2 *Test*
Total No. of preterm births	89	55	
Apgar score ≤6			
1 min	57 (64%)	27 (49.1%)	p = NS
5 min	39 (43.8%)	11 (20.0%)	$p < 0.025$
RDS	44 (49.4%)	11 (20.0%)	$p < 0.025$
Neonatal infection	22 (24.7%)	8 (14.5%)	$p < 0.05$
Neonatal acidosis	20 (22.5%)	4 (7.3%)	$p < 0.025$
Hyperbilirubinemia	29 (32.6%)	13 (23.6%)	p = NS
Hypoglycemia	39 (3.4%)	5 (9.1%)	p = NS

RDS, Respiratory distress syndrome. Neonatal acidosis, pH <7.20. Hyperbilirubinemia, serum bilirubin level >10.0 mg/dl. Hypoglycemia, plasma glucose level <30.0 mg/dl.

Eighteen high-risk factors that my be attributed to the development of fetal growth retardation were found in 80% of symmetric and 70% of asymmetric IUGR in our study population. Our data are consistent with Galbraith et al.,[2] who found that two thirds of IUGR infants come from the population with risk factors. It is interesting to find that an almost equal incidence of symmetric and asymmetric IUGR infants were produced by pregnancies associated with such high-risk factors as chronic hypertension, anemia, antepartum hemorrhage, and twin gestation. These factors were previously thought to be related only to the production of asymmetric IUGR.[2,3,17] In addition, more symmetric than asymmetric IUGR infants were associated with preeclampsia. The majority of the preeclampsia cases in this study series, however, was cases involving either an early onset of preeclampsia (before 32 weeks of gestation) or chronic hypertension with superimposed preeclampsia. The extremely poor fetal outcome seen in severe cases of preeclampsia during midpregnancy and in chronic hypertension with superimposed severe preeclampsia has been well documented.[18,19] The preterm growth-retarded fetus so produced resembles symmetric rather than asymmetric IUGR in its appearance.

On the basis of the results of the present study, medical, obstetric, and environmental-behavioral high-risk factors do not produce predominantly symmetric or asymmetric IUGR infants. We speculate that the timing of the interaction between high-risk factors and the stage of gestation, rather than the nature of each high-risk factor, plays the more important role in determining whether symmetric or asymmetric IUGR will occur in human pregnancies.

Intrauterine fetal growth can be viewed as series of incremental changes in the size of the fetus, as well as in the function of various fetal organ systems, throughout the entire period of pregnancy. These changes are influenced by both genetic and environmental factors, which interact with cell proliferation, organ differentiation, and metabolic development in the process of fetal growth. On the basis of animal experiments and human observations, Rosso and Winick[17,20] have described three phases of fetal cellular growth. The first phase is cellular hyperplasia, which includes an increase in cell number occurring during the first 16 weeks of embryonic and fetal life. Fetal insult during this phase leads to the development of symmetric IUGR with the primary effect being a reduced cell number. These infants are usually small in size with a reduction in all external measurements, e.g., weight, length, and head circumference, thus producing a normal ponderal index. This type of growth retardation is frequently associated with congenital malformations. The second phase of fetal growth is concomitant hyperplasia and hypertrophic cellular growth. This phase encompasses the period from 16 to 32 weeks' gestation, during which time there is progressive decrease in the rate of cell hyperplasia and a progressive increase in hypertrophic cell growth. Fetal insult during this phase usually produces a mixed or intermediate type of IUGR with features resembling symmetric IUGR if the insult occurs earlier and asymmetric IUGR if the insult occurs in the latter half of this phase. The third phase of fetal growth extends from 32 weeks to term. During this time period, cell size rapidly increases, along with the rate of glycogen and fat deposition. An insult during this phase leads to the development of asymmetric IUGR with its relative brain-sparing phenomenon. This well-known hypothesis serves as a basis to support our speculation that the timing of the interaction between high-risk factors and the stage of gestation is far more important than the nature of each high-risk factor. Thus a symmetric IUGR fetus can be produced by the pregnant woman with an early onset of severe preeclampsia.

Approximately one third of both the symmetric and asymmetric IUGR cases in our study series were identified by prenatal examination and subsequent ultrasonographic examination during pregnancy. Using serial ultrasonography for prenatal detection of IUGR in a large study population in London, Warsof et al.[21] were able to detect IUGR with an accuracy of 68%. Hughey[22] was able to detect only 23% of IUGR fetuses by means of clinical methods and selective screening, but he was able to increase his IUGR detection rate to 57% by using routine ultrasonographic screening. The relatively low prenatal IUGR detection rate in this study series is mainly due to the fact that routine ultrasonographic screening is not performed on our entire obstetric population.

The major findings in the comparison of perinatal outcome between symmetric and asymmetric IUGR in this study series include: (1) that the onset of symmetric IUGR occurs much earlier in the course of pregnancy than that of asymmetric IUGR, (2) that more symmetric than asymmetric IUGR results in preterm delivery, (3) that the morbidity rate for symmetric IUGR is higher than that for asymmetric preterm IUGR neonates, and (4) that term symmetric IUGR infants tend to have a lower body weight and a smaller placenta than do term asymmetric IUGR infants.

Recently, investigators[23,24] have paid special attention to the preterm growth-retarded infant because, in general, infants in this category have the worst prognosis. In addition to the knowledge of a worse prognosis for preterm IUGR than for preterm appropriate-for-gestational-age infants, this study has further documented that the neonatal morbidity rate among preterm symmetric IUGR infants is significantly higher than that of preterm asymmetric IUGR infants. However, some of these differences in neonatal morbidity rates may be attributed in part to the difference in preterm birth rate observed between the two groups.

Editors' note: This manuscript was revised after these discussions were presented.

Discussion

DR. ALFRED B. KNIGHT, Temple, Texas. This article is a review of IUGR newborns in a data base of 22,616 patients delivered between 1979 and 1985. I have presumed in this discussion that information was collected on all patients in the data base.

There many complex issues regarding abnormal fetal growth yet to be answered, not the least of which is the definition.[1] The further classification of IUGR as symmetric or asymmetric was an attempt to associate cause and prognosis after the child was born with a gestational pathophysiologic condition. This concept could then be extended to in utero diagnosis. Lin and colleagues were unable to confirm the classic clinical association of certain diseases of fetus and mother with specific subtypes of growth retardation. Clarification of a number of issues relative to the patient data base and patient selection would be helpful before we discard two decades of elegant teaching of the pathophysiologic features of IUGR.

1. Dr. Lin and colleagues have used the definition of IUGR to be a birth weight for gestational age of <10th percentile. I would have anticipated that the number of infants identified would approach 10% of the data base, at least markedly greater than the 3.2% screened. Why is there such a low incidence of IUGR in their population?

2. The method for assigning gestational age was not elaborated in this manuscript and remains a critical element to the definition of IUGR. Both obstetric and neonatal information can be used, but neither can assign gestational age with a greater accuracy than plus or minus 2 or 3 weeks (excluding those patients with "stellar" dates). Perhaps an even greater error is introduced with Dubowitz gestational ages <34 weeks complicated by IUGR.[2] What method was used to determine gestational age?

3. Symmetric versus asymmetric IUGR is defined by a head circumference of >10% or <10%. Others in the newborn period have used the 25th percentile. The characterization of IUGR of differing symmetry reflects an attempt to understand and categorize causes of IUGR. In fact, rarely does a fetus-newborn have purely symmetric or asymmetric IUGR; more commonly, the condition would be considered "mixed," particularly at gestational ages of <34 weeks.[3] How many newborns were close to that asignment?

4. Risk factors for adverse fetal outcome were identified for comparison. Many are not independent factors, such as young age and pregnancy-induced hypertension. Other factors are poorly correlated with IUGR (e.g., urinary tract infection, anemia, maternal age >35 years) and still others could be more completely defined (poor obstetric history, antepartum hemorrhage, poor weight gain). More refined groupings might unmask significant correlations.

5. These high-risk factors were compared by χ^2 analysis with little significance identified. However, it would have been useful to evaluate the difference between the population of IUGR patients and the general data base to confirm that this population was indeed unique.

6. Perinatal events and fetal outcome would benefit from more detailed assessment. For example, the single category "intrapartum fetal distress" includes meconium-stained amniotic fluid, abnormal fetal heart rate patterns, and fetal acidosis. These three clinical findings may be independent and may or may not reflect "distress" or fetal compromise.

Differences in 5-minute Apgar score and neonatal death rate were statistically significant between the symmetric and asymmetric groups. However, the symmetric IUGR newborns were more likely premature. Is this association simply a reflection of prematurity?

In summary, Dr. Lin and colleagues have presented interesting material from a large perinatal data base. With their patient selection no antepartum maternal or fetal factors clearly differentiated symmetric from asymmetric IUGR. I look forward to additional analysis of this information.

DR. L. WAYNE HESS, Jackson, Mississippi. Dr. Lin's article leaves several questions unanswered, including the following: (1) What percent of cases of antenatally suspected IUGR did not have IUGR postnatally (per Dr. Lin's definition)? (2) Was there a difference between the outcomes of the 227 antenatally diagnosed and 491 postnatally diagnosed IUGR infants; i.e., did antenatal intervention improve outcome? (3) How was the control group defined for Fig. 2? (4) What was the power of the statistics for Tables I to IV to conclude there were no statistical differences?

Additionally, the study could be strengthened by the addition of a case-matched control group. A recent study contrasted all IUGR infants with a case-matched control population.[1] However, this study failed to contrast type I and type II IUGR infants to the control population. To date, no other large series has contrasted type I and type II IUGR infants to a control population.

Dr. Lin's article provides the clinician some new insights into the problem of IUGR. However, it leaves the clinician with three problems that are difficult to reconcile. First, the clinician is interested in abnormal growth, not birth weight. A birth weight at the 10th percentile will not always define abnormal fetal growth.[2] A postterm fetus that is severely malnourished will frequently have a birth weight >10th percentile. Second, previous studies that have "established" the 10th percentile for birth weight have demonstrated great variability in results, mainly on the basis of population differences. Lubchenco et al.[3] established neonatal growth curves on the basis of 5635 Denver (high-altitude) hospital births occurring between 1948 and 1961. The "dates" in this study were based on mother's last menstrual period without correction for clinical criteria. Nonwhite and diabetic patients were excluded from the study. Goldenberg et al.[4] noted a 192 gm (at 28 weeks) to 823 gm (at 42 weeks) difference in the 10th percentile birth weights in 38 summarized studies. Third, defining IUGR as a birth weight <10th percentile assumes: (1) that adverse outcome and birth weight percentile remain constant at all gestational ages and (2) that the 10th percentile is a meaningful, discrete cutoff level. Myers and Ferguson[5] have demonstrated that neither of these assumptions is true. The birth weight percentile at which the stillbirth rate is quadrupled is the 1.5th percentile at 28 weeks versus the 16.5th percentile at 42 weeks. IUGR must be more objectively defined before standard obstetric interventions or newly suggested therapies (such as fetal substrate augmentation with nutrients and oxygen or low-dose maternal aspirin therapy) can be objectively, scientifically evaluated.

DR. DANIEL A. RIGHTMIRE, Springfield, Illinois. I am quite curious as to why Dr. Lin did not use a head circumference/abdominal circumference ratio in his definition of symmetric versus asymmetric growth retardation. Head circumference, compared to abdominal circumference, may be a late indicator of poor fetal growth.

Think of the causes of growth retardation as being divided into placental factors, maternal factors, and fetal factors. I am afraid that Dr. Lin's definition may have preselected a group of small-to-be fetuses who had fetal factors early on, either pathologically or normally. In other words, he may have a mix of constitutionally small babies who will do well and babies with birth defects or other constitutional factors, all of whom may be predetermined to be small throughout pregnancy.

I am afraid that many of his findings might be simple, logical extensions of his definitions rather than reflections of pathologic conditions of gestation.

TRANSACTIONS OF THE FIFTY-SEVENTH ANNUAL MEETING OF THE PACIFIC COAST OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The issue of animal rights and human rights

Presidential address

James M. Maharry
Whittier, California

Those of you who are involved in biomedical research are well aware that animal rights activists have mounted a concerted effort to deny the use of animals in research endeavors. Biomedical research efforts are under attack in the press and electronic media. There have been acts of violence in laboratories. Efforts to obtain research animals and the funds necessary to carry out studies have been compromised by intense lobbying efforts in the U.S. Congress and in the universities.

Two years ago after being named president-elect of this meeting, I selected "animal rights" as the topic for the presidential address. This presented a small problem. I, like most clinicians, knew almost nothing about the subject. To acquire the knowledge needed to address the topic, a simple pseudoscientific study was designed and carried out. The material and methods used, results obtained, and comments will constitute my presidential address.

First, however, the bias of the investigator should be firmly established. To do this, a short autobiography is presented. I was born and reared on a farm in Iowa, where an early Sunday morning ritual was for the children to catch several chickens for my mother to kill for Sunday dinner, a meal prepared and served when the family returned from church in the early afternoon. One of my earliest and most vivid memories occurred on such a Sunday morning. After catching and handing a chicken to my mother, I watched as she wrung its neck. After the neck was wrung and with the head still in my mother's hand, the chicken's body flew through the air to land upright and run across the barnyard for 10 or 15 feet before it collapsed. I stood transfixed until I heard my mother's voice: "Jimmy! For heaven's sake, go pick it up."

My parents had a firm belief in God, and their daily conduct reflected biblical teaching. There was no doubt in their minds that God had given Adam and Eve dominion over all the animals. Along with this right of dominion, they felt a deep moral obligation to humanely care for their animals. Our farm animals were fed, watered, and sheltered from the elements. If ill or injured beyond human help, they were humanely destroyed.

We always had a watchdog that helped with the livestock. He was never allowed in the house, and he subsisted on table scraps and what food he could forage. Off limits to him were chickens and the barn cats. Cats lived in our barn and were expected to sustain themselves by ridding the barn and grainery of rodents. Rodents were not trapped or poisoned. If they could avoid the cats, they were allowed to live. In the 1930s when the government was paying farmers to destroy and bury their livestock, my father refused to join the program. "It was against the nature of things," he said.

We hunted pheasant and ducks in season and rabbits the year-round. When not hunting we fished. Hunting and fishing were not for the sake of the kill but for putting food on the table. We were taught the reverence for life and the interdependence of one life form on another form of life.

My experience in animal research has been limited to the classroom laboratory. In undergraduate school, cadavers of dogfish and domestic cats were dissected in the study of comparative anatomy. In medical school, I learned to pith a frog and euthanize a rabbit by the intravenous injection of a bolus of air. On looking back, I studied remarkably few living animals; most of my time was spent trying to properly smoke a kymograph drum. The medical school I attended did not use live dogs for teaching students; however, live dogs were used in the research laboratory.

I have not hunted or fished since leaving the farm. On acquiring our first home, we adopted the first of our many pet dogs. Our pet dogs have lived in the house as members of the family and forage for food only as far as their bowl on the patio. I must confess

to occasionally trapping a gopher in the garden, and I once hired an exterminator in a futile attempt to rid our avocado trees of rats.

Material and methods

The true meaning of this scientific heading has been corrupted. For this study it describes the four methods used to obtain material necessary to educate the investigator.

Method 1. Small monetary donations were made to two animal rights groups.

Method 2. An office employee was assigned the duty of spending several hours each week in the morgue of the *Whittier Daily News*, our local newspaper. Her duty was to make copies of press accounts concerning animal rights published since Jan. 1, 1980.

Method 3. Each new issue of the *TV Guide* magazine was studied, and a list of programs to be aired in the ensuing week pertaining to animal rights was prepared. It was my duty to view these at a later time on videotape. Reprints of programs of special interest were obtained for more intense study.

Method 4. Med-Line computer program through Presbyterian Intercommunity Hospital was requested to make a title search of the scientific literature for articles concerning the animal rights issue. Reprints of 30 scientific articles pertaining to this subject were then obtained. A copy of *The Biomedical Investigator's Handbook for Researchers Using Animal Models* was obtained from the Foundation for Biomedical Research.

These four simple methods produced a great volume of material for study.

Results

The small donations to several animal rights groups evidently resulted in the placing of my name and address on a mailing list of people sympathetic to animals, inasmuch as in a very short time six to 10 letters a month from a number of different groups began arriving in the mail. These mailings from animal rights groups, which always contained a plea for funds, can be loosely divided into two types. The first type almost always contains a graphic picture, often of a living dog that appears to have been cruelly mutilated. Another of this type pictures a wild animal held in the jaws of a steel trap. The second type of letter presents a long litany of horror stories of animal abuse. It then goes on to point out cases of animal cruelty they have exposed and their successes in bringing charges against those responsible.

A plea for funds illustrative of the first type of letter was received from the Doris Day Animal League. The package of material contained a four-page letter stating that 10 million innocent animals died horribly last year in needless experiments. It then graphically described the scene of a family pet, Skip, a beagle dog, being led to his death in an animal research facility. Skip was described as lovable, faithful, and as trusting as any family pet that ever lived. The letter leads one to believe that 10 million dogs a year are so cruelly destroyed. The package of material also contained a sealed envelope with this warning: "This envelope contains photographic evidence of the brutal mistreatment of a helpless animal. Do not open if strong, graphic material is offensive to you." The sealed envelope contained the picture of a living dog that had been cruelly mutilated. The package also contained petitions that needed only my signature to forward to my congressman and both California senators. The petitions urged the passage of a federal law to outlaw the use of pound animals in biomedical research.

The second type of plea for funds was contained in material received from the Animal Legal Defense Fund. The envelope that contained their solicitation for funds appeared similar to those received from the U.S. government. Emblazoned on the envelope was: "National Animal Rights Survey." The four-page letter informed me of my being selected to participate in a survey on animal rights. If I could answer "yes" to any of the eight questions in the survey I should send money to support their efforts to protect animals everywhere from exploitation and cruel abuse. The letter implored me to join the fight against the vast research industry that thrived on animal cruelty, noting that each year the billion-dollar industry needlessly "snuffed out" the lives of more than 50 million animals. They further noted that much of the research was funded by my tax dollars, whereas my donation to them was tax deductible. Their unique role in the animal rights movement was emphasized: "Only the Animal Legal Defense Fund has the expertise to deliver legal services that can be crucial to saving an animal's life." The letter also recounted their court room victories for animal welfare on the farm, in the wilderness, and in research laboratories.

Our research conducted in the morgue of the local newspaper produced numerous press reports concerning animal rights activity. Almost all the articles reported acts of violence against universities, biomedical research facilities, U.S. companies, and even department stores. Acts of violence or other attempts at intimidation were reported to have occurred locally, regionally, nationally, and internationally.

Local. There were frequent reports of animal rights activists gathering at Loma Linda University to protest the use of baboons to supply hearts as transplants for human infants.

Statewide. Almost $5 million of damage was caused when militant activists set fire to the veterinarian diagnostic laboratory that was under construction at the University of California at Davis. Terrorist activity intended to intimidate research at the University of California at Berkley was treated by the press as a humorous event. This is the case in which pickets mounted cranes to stop construction of a research building on the campus but chose the wrong building site.

Animal rights activists are not only challenging the right to use animals in biomedical research, agricultural scientists and producers of livestock, eggs, chickens, and milk are also under increasing attack. In Dixon, California, the last sheep auction yard in the state was shut down by a $250,000 arson fire. Earth First, a radical environmental group, claimed responsibility for the fire; they also took credit for vandalism to the California Cattlemen's office in Sacramento.

Regional. The research laboratory at the University of Oregon was damaged to the extent of $40,000, and 125 research animals were stolen. In Tucson, Arizona, a group known as the Animal Liberation Front claimed responsibility for a $100,000 arson fire at the University of Arizona. Not only were research buildings torched, but more than 1000 animals were freed. Among the animals freed were 30 young mice infected with *Cryptosporidium*, an infectious third-world disease.

National. The first act of terrorism noted in our review occurred in 1981 in Rockville, Maryland, where radical animal rights activists burglarized an animal research laboratory and removed four baby chimpanzees worth $100,000. Police in Norwalk, Connecticut, arrested a female terrorist outside of the United States Surgical Company—a company that uses dogs in the research of suture material. She was charged with attempted murder and possession of explosive devices. The head injury laboratory at the University of Pennsylvania was forced to shut down after videotapes of experiments were stolen in a burglary and made available to the public and to Congress.

International. In England, the Animal Liberation Front claimed responsibility for firebomb attacks on five of London's leading department stores. These attacks were made during the Christmas shopping season and caused millions of dollars in damage. The reason for the attacks was that the stores sold coats made from animal furs.

It is disturbing that only one press report defended the use of animals in medical research. This was found in Ann Landers' column in her answer to a reader's letter condemning animal research. She quoted Dr. David Hubel of Harvard Medical School as stating that whereas medical researchers are using other methods such as computers and cell cultures, it just is not true that there is no longer a need for animals. Hubel, who studies abnormalities in the brain that lead to blindness, uses animals and computers. He points out that unfortunately there is nothing in a computer that resembles a brain and that any research about the brain that involves a computer is based on earlier studies with animals. She also quoted Dr. Donald Kennedy, president of Stanford University, as stating that important research cannot be done today without animals. The harsh truth is that to stop research with animals would be to stop critically needed fundamental research in biology and medicine. She further quoted Dr. Michael DeBakey, who performed the first successful coronary artery bypass, who stated virtually every pioneering development in cardiovascular surgery was based on animal experimentation. In this field, as in a number of others, there is virtually no alternative to the use of animals for experimental advances.

A 1989 poll conducted by the Gallup Company reported 77% of Americans approved the use of animals for research but only 30% knew the Federal Government regulates the treatment of these animals.

The study of programs broadcast on television that concern animal rights revealed the subject was discussed primarily on talk shows. The spokesman for animal rights would be an impassioned activist detailing atrocities inflicted on helpless animals, quoting wild unsubstantiated figures as to the number of animals cruelly and needlessly destroyed, and stating that had cadavers or cultures and computer models been used, better results would have been obtained. The thalidomide tragedy was often cited to support this argument. One of the effective techniques used by animal rights groups is for their spokesman to be a celebrity who has instant recognition. In contrast, spokesmen for the biomedical research industry are professional in their manner but often appear uncomfortable. Their defense of the use of animals is always the same—without animal research none of us would enjoy the health benefits we have today.

After watching the ABC News *Nightline* television program broadcast on April 25, 1989, a reprint of the program was obtained. The three panelists on the program were a spokesman from the American Medical Association, the leader of People for the Ethical Treatment of Animals, and Jane Goodall. In the introduction to the program it was stated that there were 7000 animal rights groups with 10 million members. The spokesman for the biomedical research industry was low-key and professional, whereas the spokesman from People for the Ethical Treatment of Animals was impassioned and strident in his comments. The moderator had to frequently warn him not to interrupt the other panelists. People for the Ethical Treatment of Animals took credit for using the stolen videotapes to shut down the head injury laboratory at the University of Pennsylvania.

Jane Goodall's contribution was poignant and obviously very sincere. She acknowledged that her mother's life had been saved by a heart valve obtained from a pig. She mourns the pigs that gave their lives in research and those that would continue to lose their lives to improve human existence. Her closing remarks were that she looked forward to the day when there would be no animals held in cages.

The review of the scientific literature was undertaken only to educate this investigator. Here is a short list of some titles[1-18] representative of the type of articles being published in the scientific literature concerning animal experimentation: *The First 100 Years of Vivisection: 1824 to 1924*,[1] *William Osler and Arthur Conan Doyle Versus the Antivivisectionists*,[2] *Immoral and Moral Uses of Animals*,[3] *Science and Animal Protection*,[4] *Regulation of Animal Experimentation*,[5] *The Cost of Not Doing Medical Research*,[6] *The Case for the Use of Animals in Biomedical Research*,[7] *The Physician's Stake in Animal Research*,[8] *Rethinking the Morality of Animal Research*,[9] *The Biomedical Investigator's Handbook for Researchers Using Animal Models*,[10] *The Use of Animals in Biomedical Research*, the AMA "white paper," 1989.[11]

Comment

Historically, animal experimentation has been carried out in a very limited manner since ancient times. It only began in earnest, however, early in the nineteenth century.[1, 2] From its inception, people with concern for animals began to take notice, and in 1823 the Royal Society for the Prevention of Cruelty to Animals was founded in England. By the middle of the nineteenth century, opposition to the use of animals was well organized. This organized opposition was labeled antivivisectionism. At about this time in France, Claude Bernard, the founder of physiology, was opposed in his research efforts by his wife and daughter, who were antivivisectionist leaders. The first national law relating to animal experimentation was enacted in England in 1876. The Society for the Prevention of Cruelty to Animals was founded in the United States in 1866, and the first bill opposing animal experimentation was introduced in the U.S. Congress in 1897. The present law (Animal Welfare Act) governing animal experimentation in the United States was enacted in 1966, and last amended in 1985. This act applies primarily to cats, dogs, and subhuman primates.

This brief and incomplete history is presented only to make you aware of the long history of organized opposition to animal experimentation. Traditionally, humane societies were formed to prevent the inhumane treatment of animals everywhere, whereas antivivisectionists, now known as animal rights activists, have concerned themselves with animal experimentation.

In the past 10 years many new and militant animal rights groups have been formed, and militant activists are infiltrating long-established humane societies. In taking over humane societies long-established endowments will be available to them.

Over the past 10 years, the rhetoric of animal rights activitists has become increasingly violent. This violent rhetoric is stimulating those on the lunatic fringe of society to commit the acts of terrorism that are increasingly reported. It has been said violence in the voice is often only the death rattle of reason in the throat. On television talk shows, panelists and some of the audience applaud acts of violence committed by militant activists. Violence in the support of any cause is an act of terrorism. Those responsible for burglary, arson, or any other criminal act should be prosecuted, not applauded, for their illegal behavior.

This is not intended to be a blanket condemnation of all animal rights groups or their well-meaning members. For more than 150 years the organizations with genuine concern for the welfare of animals have served as the conscience of society. The old cliche that if you eat them or wear them you have no moral right to oppose their use in biomedical research should never be used in the defense of animal experimentation. That argument is simplistic, undignified, and simply not true. The vast majority of the members who peacefully support these groups with their time and money have every moral right to do so.

The danger in all of this is the recent and rapid evolution of a huge animal rights industry, an industry probably far larger in numbers than the biomedical research industry. Opportunists are forming new groups and others are infiltrating established ones. In an effort to attract new members and new donations, they are using the most modern techniques. These techniques include mailing lists, bulk mailings, public relations firms, and fund-raising organizations. I recently watched my first national television commercial presented by People for the Ethical Treatment of Animals. The animal rights industry is big business with the so-called cruelly exploited and defenseless animal as the centerpiece. There is a concerted effort by the Animal Legal Defense Fund to be named as the legal surrogate for animals. If they are successful they can sue in court for monetary damages on behalf of animals.

Unfortunately for society, no one in organized medicine or in biomedical research seems willing to able to oppose such efforts. If you examine the scientific literature on the subject of animal rights you are overwhelmed by its sheer volume. On reading this literature one is immediately impressed by the depth of soul searching evident in the text of many of the articles. Unfortunately, there is a fatal flaw contained in this vast literature concerning animal rights—researchers and members of the medical profession are just talking to each other. A perfect example of this fact is occurring here today. After almost 2 years of study, I am speaking to a collection of 200 people, most of whom are already sympathetic to animal experimentation. If, by chance, these remarks are published, it will be in a journal primarily read by those who practice obstetrics and gynecology. Few will read it.

The biomedical research industry and the medical profession may be under a siege more grave than even the industry itself realizes. Translating the percentages from the Gallup Poll[17] into population figures reveals: 60 million Americans do not approve the use of living animals in research, and 150 million know almost nothing about the subject. This may portend an ominous future for society.

Something must be done about the fact that in our scientific literature we are only talking to each other. Unfortunately, we only listen when the subject directly concerns us. Why shouldn't we adopt the same modern techniques being used against us? There is nothing evil or unethical about using mailing lists, bulk mailings, public relations experts, or even fund-raising organizations in the name of education. Effective speakers should be recruited from the medical profession to carry our case to the public. The biomedical research industry has genuine concern for animals used in necessary experimentation; *The Biomedical Investigator's Handbook*[10] and the vast literature on the subject amply demonstrate this fact. Researchers use in vitro rather than in vivo methods whenever possible; three of the four largest cosmetics companies have just abandoned the Draize test and have gone to an in vitro test.

The American public is a reasonable body and would accept a truthful recounting of the prodigious advances in biological and medical knowledge that have resulted from the necessary use of animals in biomedical research. The public needs to realize *there is not a single modern and substantial item of medical knowledge that does not owe something to animal experimentation.* The health and welfare of animals has improved markedly as a result of experimentation.

When a movie or television personality has a successful by-pass surgery, we should not hesitate to let society know of the role animals played in the development of the surgical procedure. Professional athletes who have insulin-dependent diabetes are praised for their courage. Without animal experimentation there would be no insulin to control the disease. Parents of young children need to know of the role animals played in the development of the vaccines that protect all of society from recurrent epidemics. The public needs to be informed of the role animals play in the safety of the medications they use in their daily lives. After development and release to the public, all drugs and biologicals are subjected to continued testing on animals to ensure their safety; this testing is mandated by federal law. Companies that produce chemicals used in household products are mandated by law to certify their safety. This requires that large numbers of animals be killed to carry out the lethal dose 50 test. Cosmetics companies must certify their products to be safe for human use; this testing, again with the use of animals, is mandated by federal law.

The number of animals killed each year in biomedical research and product testing can only be estimated, but whatever the exact number, at least 90% are rats and mice. Dogs make up less than 2% of the total. The fact that 15 million household pets are killed each year in the name of animal control by the local animal pound elicits only a feeble public outcry.

At times one has to research the so-called comic strips to discover pointed social commentary. The following is a dialog between Sir Rodney and the King in a strip from the *Wizard of Id.* Sir Rodney addresses the King who is seated on this throne, "Sir! You have to do something for the homeless!" The King answers, "Where am I going to get the money?" Sir Rodney replies, "Could we cut back a bit on the new animal shelter?" The priorities of our society are such that the picture of an injured animal elicits a stronger humanitarian response than do pictures of the homeless huddling on the streets or tiny children dying of starvation in Ethiopia.

I respect the moral right of a person to protest the use of animals in biomedical research or product testing, but how much better the world would be if their efforts and money were directed toward making shelter available for the homeless, food available to the hungry, a guarantee of safety for all drugs and products used by animals and human beings, and a cure for all the diseases that plague both animals and man.

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is $64.50 ($69.00 international). Prices include shipping. *Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.*

Lymphocytic adenohypophysitis: A pituitary mass lesion occurring in pregnancy

Proposal for medical treatment

Seth L. Feigenbaum, MPH, MD,[a] Mary C. Martin, MD,[a] Charles B. Wilson, MD,[b] and Robert B. Jaffe, MD[a]
San Francisco, California

Lymphocytic adenohypophysitis is a nonneoplastic, autoimmune cause of pituitary enlargement and insufficiency. Forty-eight of the 50 reported cases have occurred in women, nearly all in association with pregnancy. Left undiagnosed and untreated, it can progress to pituitary insufficiency and death. Histologic studies show characteristic changes of autoimmune disease with lymphocytic infiltration and destruction of anterior pituitary tissue with fibrotic replacement. Lymphocytic adenohypophysitis is currently diagnosed after other pituitary mass lesions are excluded and has been treated with a combination of neurosurgery and end-organ hormone replacement. However, with improved knowledge of the pathophysiologic characteristics and natural history of the disease and with the ability to make a prospective diagnosis, we believe glucocorticoids may suppress the inflammatory response and protect remaining pituitary tissue. Two previously unreported pregnancy-associated cases are described, including one prospectively diagnosed and treated without neurosurgery during pregnancy. Obstetrician-gynecologists must place lymphocytic adenohypophysitis in the differential diagnosis of pituitary enlargement associated with pregnancy, since treatment is available and the sequelae may be life-threatening. (AM J OBSTET GYNECOL 1991;164:1549-55.)

Key words: Lymphocytic adenohypophysitis, pituitary, pregnancy complications, neurosurgery, pituitary insufficiency

Lympyhocytic adenohypophysitis is a nonneoplastic, autoimmune cause of pituitary enlargement and insufficiency. Of 50 reported cases in the world literature, 48 have occurred in women, and nearly all have occurred during pregnancy, the puerperium, or the first postpartum year. Despite this association with pregnancy, there is rare mention of this disease in the obstetric and gynecologic literature. If left undiagnosed and untreated, it can progress insidiously or quickly to pituitary insufficiency and death. Obstetrician-gynecologists and neurosurgeons must therefore include lymphocytic adenohypophysitis in the differential diagnosis of pregnancy-associated pituitary enlargement. Often mistakenly diagnosed as a prolactin-secreting adenoma, the etiology, pathology and therapy of the two differ fundamentally. Lymphocytic adenohypophysitis is currently treated with a combination of neurosurgery and end-organ hormone replacement, often resulting in significant chronic morbidity, whereas prolactin-secreting adenomas may be more easily managed medically and usually without long-term sequelae. With improved knowledge of the pathophysiology of lymphocytic adenohypophysitis, the ability to make a prospective diagnosis among symptomatic peripartal women, and recently acquired experience in treatment, we believe that a trial of medical therapy may be warranted before routine neurosurgical exploration is performed. We report here our experience with two previously unreported cases of this unusual cause of pituitary enlargement in young peripartal women including the first case prospectively diagnosed and treated without neurosurgery during pregnancy.

Case reports

Case 1. A 26-year-old primiparous woman was seen, 1 month after uncomplicated vaginal delivery, with a 2-month history of daily midline frontal headaches accompanied by diplopia and gradual decrease in visual acuity. During the postpartum period, she had failure of lactation and complained of lethargy and low-grade fever. Her medical history, including gynecologic, was noncontributory. Physical examination revealed bitemporal field defects to confrontation, left greater than right, with acuity of 20/60 on the left and 20/40 on

the right. A computed tomographic (CT) scan showed a large pituitary mass with suprasellar extension. Laboratory evaluation demonstrated hypopituitarism; insulin-induced hypoglycemia resulted in a basal cortisol level of <1 μg/dl with no increase after stimulation and a growth hormone level of 3.1 ng/ml with no increase. Thyrotropin-releasing hormone challenge (200 μg given as an intravenous bolus) resulted in a prolactin increase from 4 to 8 ng/ml; a gonadotropin-releasing hormone challenge (100 μg) was followed by a luteinizing hormone rise from 4 to 10 mIU/ml, a follicle-stimulating hormone rise from 9 to 20 mIU/ml; and decreased thyroid function (thyroxine index, 0.9; thyroxine, 3.7 μg/dl; triiodothyronine, 23.5 ng/dl). An autoantibody screen was negative, including antinuclear antibodies, latex fixation, antithyroglobulin, and antimicrosomal antibodies. The hypopituitarism was attributed to either a pituitary adenoma or adenohypophysitis. With corticosteroid coverage, transsphenoidal pituitary exploration was performed. A large, dull, white, tough mass extending almost 2 cm above the sella was subtotally removed. Histologic examination showed infiltration and destruction of anterior hypophyseal acini with lymphocytes and plasma cells (Fig. 1, *A*) and replacement of normal glandular tissue with lymphoid aggregates and fibrosis (Fig. 1, *B*). After operation the patient's visual acuity and fields returned to normal. She was discharged and is being followed up on a regimen of hormone replacement including hydrocortisone, desmopressin acetate, levothyroxine, conjugated estrogens, and medroxyprogesterone acetate.

Case 2. A 30-year-old multiparous woman was admitted to the hospital in her thirty-fifth week of gestation with a complaint of blurred vision. Her antenatal course had been uncomplicated until about 6 weeks before admission, when she noted gradual onset of blurred vision in the left eye that progressively worsened; at admission she was found to have bitemporal hemianopsia. Menses had been regular before conception, and there was no history of infertility or galactorrhea. Pregnancy studies, including an ultrasonogram and nonstress tests, were normal. A CT scan showed a large intrasellar mass with suprasellar extension (Fig. 2, *A*). Laboratory analysis included normal complete blood count and SMA-12 results for pregnancy, and a prolactin level of 185 ng/ml (within normal limits for 35 weeks' gestation). An overnight adrenocorticotropic hormone stimulation test was performed. Basal cortisol level was 9 μg/dl with a rise to 13 μg/dl. Dynamic pituitary testing was postponed until after delivery. Tests for rheumatoid factor, antinuclear, anti-double-stranded dexoyribonucleic acid, antimitochondrial, anti–smooth muscle, anti–parietal cell, antimicrosomal, and antithyroglobulin antibodies were negative. Serologic test for syphilis was negative. The differential diagnosis was lymphocytic adenohypophysitis versus pituitary adenoma. Bromocriptine therapy (2.5 mg twice daily) was started as a diagnostic maneuver and to reduce pressure on the optic chiasm. Amniocentesis was performed; the lecithin/sphingomyelin ratio was 1.8 : 1 and no phosphatidylglycerol was present. Daily visual field studies were performed and remained unchanged. After 9 days of bromocriptine therapy there was no improvement in symptoms, and a repeat CT scan was obtained that showed no change in the size of the mass. Prednisone therapy (2.5 mg three times a day) was instituted. Nine days later, after completion of 37 weeks' gestation, the patient was delivered of a 3360 gm infant after an uncomplicated induction of labor. She was maintained on a regimen of prednisone. During the first postpartum week her clinical condition and visual fields remained unchanged, and she lactated normally without breastfeeding. One week after delivery, vision began to improve and subsequently returned to normal. A CT scan performed at that time revealed a decrease in the size of the mass, although significant enlargement persisted. Menses resumed 3 months post partum without breastfeeding. CT scan performed at that time showed a significant decrease in mass size (Fig. 2, *B*). Dynamic pituitary testing was performed 5 months post partum, after tapering and temporarily stopping steroid therapy for 6 weeks before testing; insulin-induced hypoglycemia showed undetectable growth hormone before and after stimulation and a cortisol level of 4 ng/dl with no rise, a thyrotropin-releasing hormone challenge showed a rise in prolactin level from 79 to 357 ng/ml, and a gonadotropin-releasing hormone challenge resulted in a luteinizing hormone rise from 10 to 91 mIU/ml and a follicle-stimulating hormone rise from 7 to 25 mIU/ml. She has been maintained on a regimen of prednisone and is having regular menses. Human leukocyte antigen haplotypes were A28, Aw24(A9), Bw44(B12), B7, Cw7, Dr2, Dr5, MT1, MT2, and MT4.

Comment

Management of uncommon diseases that occur during pregnancy has been enhanced by better prospective diagnosis and knowledge of the pathology and natural history of these conditions. Enlargement of the pituitary gland during pregnancy is one such area in which recent anatomic and laboratory studies have contributed to more specific diagnosis and, for some pituitary mass lesions (e.g., prolactin-secreting adenomas), a change from primarily neurosurgical management to medical treatment. In a young pregnant woman with a large expanding pituitary lesion, the most common diagnosis remains a prolactin-secreting adenoma. However, the differential diagnosis must also include lymphocytic adenohypophysitis. The importance of making this diagnosis prospectively is underscored by the natural history of the disease, which has resulted in death in 25% of patients reported with this disease, including the first five in whom it was recognized at autopsy. In a recent review of 35 English language cases, individual patient presentations were summarized.[1]

Presentation. Lymphocytic adenohypophysitis is a

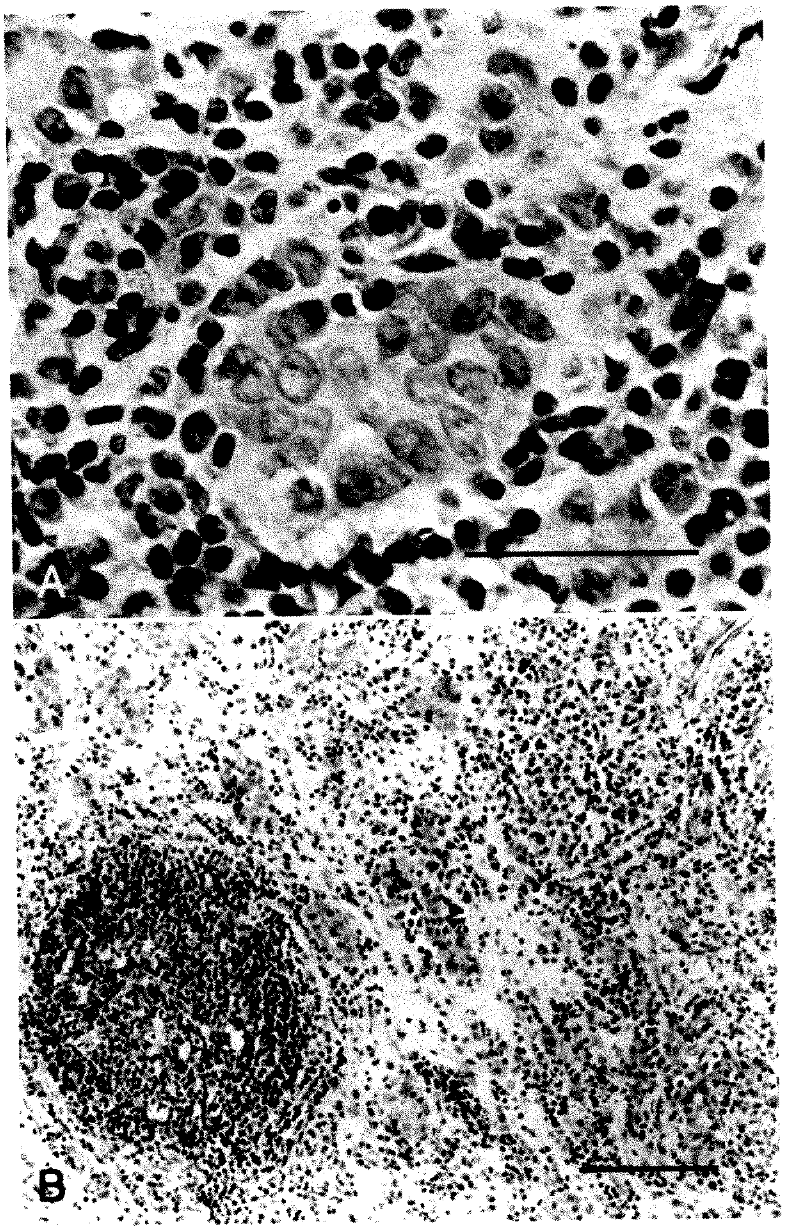

Fig. 1. A, Pituitary acinus surrounded by lymphocytes and plasma cells. (Hematoxylin and eosin. Original magnification ×343; *bar* = 100 μm.) **B,** Lymphoid aggregates in the anterior pituitary with destruction of normal tissue and replacement by fibrosis. (Hematoxylin and eosin. Original magnification ×205; *bar* = 100 μm.)

disease predominantly of women (96% of all reported cases). The youngest reported case occurred in a 17-year-old,[2] and the oldest in a 69-year-old; the median reported age at diagnosis was 28 years. Both men[3, 4] were diagnosed in their fifth decade of life. Lymphocytic adenohypophysitis is reported most often in association with pregnancy; 65% of reported cases were multiparous women and 35% had disease associated with a first pregnancy. But it has been reported in women who have never been pregnant (6% of cases). The majority of pregnant patients present with symptoms during the last trimester, although it has been reported in all trimesters. No racial predilection has been detected. The presentation appears to correlate with the apparent stage of the disease process at time of diagnosis. In nearly every case in which diagnosis is made in a living patient, presenting complaints are referable to mass effects of headache and visual changes, symptoms caused by the inflammatory infiltrate, and resulting edema of the pituitary gland. When the condition is not diagnosed antemortem, most patients have had progression to lethargy, anorexia, hypoglycemia,

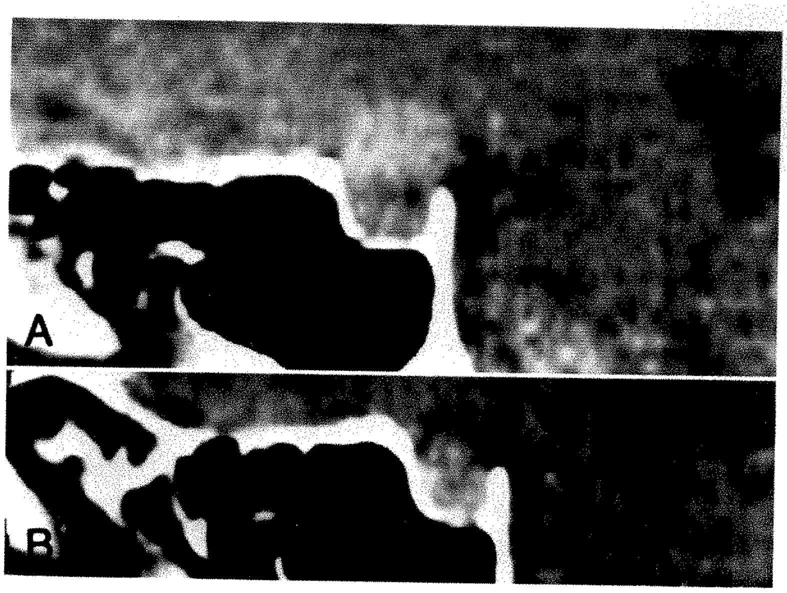

Fig. 2. A, CT scan through sella turcica of case 2 at initial presentation, 35 weeks' gestation. **B,** Case 2 at 3 months post partum with corticosteroid therapy. Significant decrease in size of mass is evident compared with 2, **A.**

and frank secondary adrenal insufficiency as a result of acute or chronic hypopituitarism. Most recent reported cases have had at presentation symptoms of a space-occupying sellar lesion, i.e., visual disturbances with or without headaches, rather than symptoms associated with adrenal insufficiency. This was the case for the four patients treated at this institution, including two previously reported.[5] In spite of the presenting symptoms referable to cranial compression, 75% of reported peripartal cases of lymphocytic adenohypophysitis had some evidence of partial or panhypopituitarism at some time during pregnancy or the postpartal period, although endocrine evaluation was incomplete in many. Among pregnant patients with sufficient reported information, hypoadrenalism (78%) and thyroid dysfunction (72%) were the most frequent abnormalities found. Primary thyroiditis diagnosed at autopsy or by clinical and laboratory criteria was found in six patients. Some patients may have only isolated defects of a single pituitary factor, e.g., adrenocorticotropic hormone. Measurement of gonadotropins and prolactin is not useful for making the diagnosis of lymphocytic adenohypophysitis during pregnancy but may be helpful in nonlactating (seven cases) and amenorrheic (nine cases) women after an interval following delivery. Only two cases of posterior pituitary dysfunction before neurosurgical intervention have been reported.[6, 7]

Anatomy and pathology. Lymphocytic infiltration of the anterior pituitary occurs rarely. Shanklin[8] examined 100 unselected human pituitaries and found a 43% incidence of lymphocytic infiltration, but this was confined entirely to the pars intermedia and pars nervosa with no involvement of the anterior lobe. Simonds and Brandes[9] reported the presence of lymphocytes in the anterior pituitary of two of 200 patients with sudden death. These series are in marked contrast to a recent report[10] describing mild lymphocytic adenohypophysitis in five of 69 autopsy-obtained pituitaries from women who died during pregnancy, after abortion, or during the postpartum period and emphasizing the association of lymphocytic adenohypophysitis with pregnancy. However, it was not clear how the lymphocytic adenohypophysitis related to each patient's illness.

Enlargement of the pituitary gland is a normal component of the anatomic and physiologic changes that occur during pregnancy[11] and is due principally to hyperplasia of prolactin-secreting cells,[10] but such enlargement does not normally induce symptoms of a space-occupying cranial lesion. Our cases were diagnosed with CT technology. In 27 of 30 patients (90%) having CT scans, a sellar lesion was demonstrated at the time of initial scan. Use of polytomography (eight abnormal in eight cases) and plain skull radiography (seven abnormal in 14 cases) has also been reported, and magnetic resonance imaging has been used in the evaluation or follow-up of six patients with lymphocytic adenohypophysitis.[1, 12] In nearly all abnormal radiologic studies of lymphocytic adenohypophysitis, a suprasellar component was demonstrated, regardless of the imaging technique used. Radiologic features have been reviewed in detail by Levine et al.[13] and Miura et al.[7]

The operative specimens obtained by transsphenoidal resection at our institution were similar to those described in the literature, i.e., firm or tough, dull white-yellow, and adherent to the surrounding structures. Histologic examination showed lymphoid infiltration, diffuse and in aggregates, and fibrosis that nearly completely obliterated normal pituitary architecture. No abnormal cells or oncocytic transformation was recognized. Numerous reports have demonstrated the presence of all major T-lymphocyte subpopulations, as well as plasma cells, in these lesions, by means of immunohistochemical staining techniques specific for surface markers and presence of κ–light chains. Review of reported postmortem cases supports the observation that the degree of replacement of normal glandular tissue with lymphocytic infiltrate is correlated with the stage of the disease process at the time of death. Those patients in whom sudden death was preceded by fatigue, anorexia, confusion, weakness, and shock most often had an atrophic gland at autopsy. An enlarged infiltrated pituitary gland also may be found in conjunction with atrophic adrenal glands.

Association with autoimmunity. The nature of the histologic findings and the natural history of lymphocytic adenohypophysitis suggest an autoimmune etiology. The histologic characteristics seen in the pituitary are similar to those seen in other autoimmune diseases, i.e., lymphocytic infiltration, obliteration of glandular tissue, and replacement of normal tissue with fibrosis. Many patients also have autoimmune-mediated inflammatory involvement of other organs, including thyroiditis,[2, 14] pancreatitis, parathyroiditis, pernicious anemia, adrenalitis, and connective tissue inflammation. In one patient[12] sarcoidosis of the eye and lung developed 6 months after diagnosis of lymphocytic adenohypophysitis associated with the birth of her second child. Too few human leukocyte antigen haplotypes have been reported to reveal specific genetic associations, although Bw35, found in increased frequency in autoimmune disorders, was reported in two of four cases when tissue typing was performed.

One classification scheme[15] defines a process as an autoimmune disease if it fulfills three criteria: (1) detection of circulating autoantibodies to a recognized specific antigen, (2) the production of similar pathologic changes in an experimental animal model produced by injection of antigen, and (3) transfer of the disease by immune serum or cells. In general, patients with lymphocytic adenohypophysitis have had negative general antibody screens, but most have not been screened for antipituitary activity. Antipituitary antibodies have been difficult to demonstrate in patients with lymphocytic adenohypophysitis in whom these studies have been attempted. Difficulties have resulted from the small amount of material obtained from operation, low apparent titers of specific antibodies, and nonspecific binding. Specific antipituitary antibodies have been found in three of six patients tested, but antibodies were not found in patients in other reports. Autoantibodies to the pituitary also have been reported in 23 of 128 unselected postpartum women in one study.[16] In that study, in 25% of 16 antibody-positive postpartum women available for follow-up, some symptoms of pituitary insufficiency developed. Experimental animal models of lymphocytic adenohypophysitis have been described. Levine[17] produced adenohypophysitis in adult rats with injection of adjuvant and pituitary lymphocytic infiltrate. From preliminary experiments, he suggested that the severity of the process was increased in postpartum animals.

Differential diagnosis. Lymphocytic adenohypophysitis must be considered in the differential diagnosis of women in the peripartum period with symptoms consistent with a space-occupying cranial lesion. In addition to sella imaging and visual field evaluation, laboratory studies including electrolytes, thyroid function tests, and a basal and adrenocorticotropic hormone–stimulated cortisol should be obtained promptly during pregnancy. A CT scan yields better information for prospective management compared with conventional radiologic studies, although the radiation exposure is somewhat higher. Magnetic resonance imaging poses no known risk to the fetus or mother and, if available, may be expected to yield information helpful in distinguishing lymphocytic adenohypophysitis from other pituitary masses. Bromocriptine (2.5 mg twice daily) should be started immediately. Initial laboratory results, sella imaging, and response to bromocriptine should suggest the direction of further evaluation and the need for prompt initiation of corticosteroid and other hormone replacement.

Postpartum women with failure of lactation and those whose menses fail to resume post partum should be closely questioned and examined for other features referable to pituitary insufficiency. In addition to sella imaging and visual field testing, an insulin-induced hypoglycemia test should be performed and growth hormone, prolactin, and cortisol concentrations assessed. A gonadotropin-releasing hormone and thyrotropin-releasing hormone challenge can be performed the same day. Since thyrotoxicosis is an occasional concomitant finding both during the peripartal period and among patients with lymphocytic adenohypophysitis, thyroid function studies should be performed and blood should be held for antibody studies.

Pituitary insufficiency may be seen in other groups of peripartum patients. Patients with postpartum pituitary necrosis, i.e., Sheehan's syndrome, can demonstrate a similar pituitary stimulation test profile. However, among lymphocytic adenohypophysitis patients diagnosed in or after labor and delivery, uncomplicated vaginal deliveries have been the rule, except for one patient in whom the disease was not suspected and who died in labor of acute adrenal insufficiency.[1] Other cases of pituitary insufficiency in association with pregnancy have been described, usually with imaging consistent with a partially empty or empty sella. Increased secretion of prolactin has been described in patients with lymphocytic adenohypophysitis and an enlarged or normal-sized[18] pituitary. This may lead the unwary to diagnose a prolactin-secreting adenoma and institute bromocriptine therapy without further investigating other pituitary trophic hormone secretion. Glycoprotein-producing pituitary adenomas, also known as nonsecretory or null-cell adenomas, may present as mass lesions, also unresponsive to bromocriptine. These adenomas may exhibit decreased pituitary trophic hormone secretion, most commonly decreased gonadotropins, and mildly elevated prolactin as a consequence of stalk compression. Increased prolactin secretion may be expected during and some weeks after pregnancy and is insufficient by itself to diagnosis a pregnancy-associated pituitary mass. Endocrinologically active pituitary tumors, e.g., growth hormone-producing tumors, usually exhibit some degree of isolated pituitary hyperfunction in association with pituitary enlargement.

Treatment. Transsphenoidal chiasmal decompression with initiation of preoperative and postoperative hormone replacement is the traditional diagnostic and therapeutic approach. However, there is reason to believe that, at least for some patients, there may be a less radical initial approach. Most patients reported in the recent literature have undergone only partial surgical resection or pituitary biopsy in the absence of marked chiasmal compression. The main benefit derived from this potentially morbid and expensive procedure may be establishment of the histologic diagnosis. However, consistent clinical features, supportive laboratory findings, and nonresponse to bromocriptine may allow a presumptive, noninvasive diagnosis of lymphocytic adenohypophysitis.

Since lymphocytic adenohypophysitis appears to share pathophysiologic features common to many autoimmune disorders, we believe that aggressive initiation of corticosteroid therapy may induce remission, as well as protect remaining pituitary tissue during periods of acute involvement. Some experience with corticosteroid therapy has been obtained. One 18-year-old woman, 10 weeks postpartum, was found to have secondary adrenal insufficiency, postpartum thyrotoxicosis, hypogonadism, and a pituitary mass with suprasellar extension.[19] Surgery was deferred due to thyrotoxicosis and because there were no symptoms referable to chiasmal compression. She was treated with cortisone acetate and propranolol hydrochloride and experienced nearly complete resolution of the mass. She continued to have chronic partial pituitary insufficiency of ACTH, growth hormone, thyroid-stimulating hormone, and prolactin production and remains on hormone replacement. At least five patients have been treated with corticosteroids in anticipation of surgical resection with improvement in signs or symptoms.[1] One patient[20] was followed after being placed on steroids when she presented in the thirty-ninth week of gestation with visual field defects. Similar to our case 2, she experienced resolution of her mass but had residual pituitary insufficiency. Another patient,[21] not operated upon, had gradual recovery of thyroid function, but not of ACTH, prolactin, or growth hormone after being placed on corticosteroids post partum.

Specific management should be determined by response to bromocriptine and steroids, as assessed by changes in visual fields, changes in mass size on imaging studies, and recovery or progression of endocrine deficits. Whether patients will be followed prospectively or undergo resection, with evidence of pituitary insufficiency of ACTH, one should not delay in instituting corticosteroids while exploring other etiologies or organ involvement. One of the two men reported with lymphocytic adenohypophysitis developed a typical adrenal crisis resulting in death while undergoing diagnostic workup for panhypopituitarism, despite being placed on corticosteroids early in the crisis.[3] Two patients gradually regained normal pituitary function after transsphenoidal decompression,[1] one patient regained normal thyroid function only,[22] and in one postpartum patient pituitary insufficiency gradually developed where none had existed before operation.[23] One suspected antepartum case of lymphocytic adenohypophysitis with selective deficiency of prolactin and growth hormone[24] continued to be deficient post partum although a pituitary mass regressed. Another patient in whom the disease was suspected, with symptoms of a pituitary mass but no hormone deficits during pregnancy, did not undergo operation. Post partum she experienced regression of the mass but later pituitary insufficiency of adrenocorticotropic hormone, growth hormone, and prolactin developed.[25] These cases underscore the rationale for continued observation and retesting of these patients. Two patients with lymphocytic adenohypophysitis have achieved a subsequent pregnancy, as would be expected with appropriate hormone replacement.

With time, acute pregnancy-associated maternal immune system alterations resolve after delivery and may enable withdrawal of steroid therapy with careful assessment of residual function. Such patients should be monitored closely for evidence of chronic or acute pituitary insufficiency and for occurrence of features associated with other autoimmune disorders. Corticosteroid therapy may not obviate the need for neurosurgical intervention in some cases of pregnancy-associated lymphocytic adenohypophysitis, but it is hoped that surgery may be reserved for patients with acute chiasmal compressive lesions that are nonresponsive to either bromocriptine or corticosteroids.

In summary, lymphocytic adenohypophysitis must be included in the differential diagnosis of pregnancy-associated pituitary enlargement. If it is diagnosed, a trial of medical therapy with corticosteroids may allow conservation of remaining pituitary tissue and decrease morbidity and costs associated with caring for patients with this unusual pituitary mass lesion.

Antibiotic treatment of tuboovarian abscess: Comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens

Susan D. Reed, MD, Daniel V. Landers, MD, and Richard L. Sweet, MD
San Francisco, California

One hundred nineteen patients with tuboovarian abscess were evaluated for response to antibiotics. Results were stratified into three groups by antimicrobial regimen. Group 1 consisted of 37 patients treated with a single-agent broad-spectrum intravenous antibiotic and oral doxycycline. Initial clinical response (defined as decreased pain, diminished white blood cell count, or defervescence) in group 1 was 31/37 (84%). Group 2 consisted of 64 patients treated with clindamycin in combination with an aminoglycoside with or without a penicillin. There was an initial clinical response in 45 of 64 (70%). Group 3 consisted of 18 patients from group 1 who were changed to a clindamycin-containing regimen after 2 to 3 days of initial treatment with a single-agent broad-spectrum antibiotic. The decision to switch antibiotics was not based on treatment failure but occurred when delayed ultrasonography confirmed the diagnosis of tuboovarian abscess. The switch reflected physician preference for clindamycin-containing regimens in the treatment of tuboovarian abscesses. The response rate in this subset of patients was 14 of 18 (78%). Overall initial clinical response rate was 90 of 119 (75%). There were no statistically significant demographic or clinical differences among the three groups. There was no statistical difference in the rate of early and late antibiotic failure rates among the groups. Our study demonstrates that extended-spectrum antibiotic coverage, including single-agent broad-spectrum antibiotics such as cefoxitin, in conjunction with doxycycline has efficacy that is equivalent to that of clindamycin-containing regimens. An overall medical treatment success rate of 75% suggests that conservative treatment of tuboovarian abscesses is warranted. (AM J OBSTET GYNECOL 1991;164:1556-62.)

Key words: Tuboovarian abscess, pelvic abscess, pelvic inflammatory disease, tuboovarian complex, antimicrobial therapy

Tuboovarian abscesses have long been recognized as a severe form of pelvic inflammatory disease that typically results from inadequate or delayed treatment of a pelvic infection. Tuboovarian abscesses are reported in 3% to 16% of hospitalized patients with acute pelvic inflammatory disease.[1] Management of tuboovarian abscesses has evolved markedly from the purely surgical approach of the preantibiotic era, which included extraperitoneal drainage with an associated high mortality from ruptured tuboovarian abscesses. When antibiotics were introduced, aggressive intraabdominal surgical approaches were used to treat ruptured tuboovarian abscesses; also antibiotics were used in the treatment of unruptured tuboovarian abscesses to "cool a patient off" in preparation for delayed surgery.[2] We are now evolving toward a more conservative approach, in which potent and broad-spectrum antibiotics are used as definitive first-line therapy and in which surgical intervention occurs only in tuboovarian abscesses that do not respond to initial antibiotic therapy.

Research on the medical treatment of tuboovarian abscess indicates that proper antimicrobial treatment of pelvic abscesses should include antibiotics that penetrate abscess cavities and remain stable in the abscess environment.[3] In particular, antimicrobial agents that provide adequate coverage against the resistant gram-negative anaerobes of *Bacteroides* group should be used. Antibiotic regimens containing clindamycin or metronidazole have generally been considered the best available agents for the treatment of tuboovarian abscesses.[1, 5] In 1983 we reported data on 321 patients with tuboovarian abscesses, only 10 of whom had been treated with one of the now commonly used extended-spectrum second- and third-generation cephalosporins.[1] The patients in that study were treated with either a clindamycin-containing regimen or a regimen with inadequate anaerobic coverage. The overall initial clinical response rate with antibiotic treatment alone was

70%, and the response rate for those treated with clindamycin (89%) was significantly better than that of patients who received non-clindamycin-containing regimens (35%). The current study compares antimicrobial regimens containing a single-agent broad-spectrum antibiotic that is effective against the resistant gram-negative anaerobes with clindamycin-containing regimens. The predominant regimens used were cefoxitin plus doxycycline and clindamycin plus gentamicin.

Methods

One hundred twenty-five patients were discharged from San Francisco General Hospital between April 1980 and January 1989 with a diagnosis of tuboovarian abscess (palpable adnexal or pelvic mass confirmed by ultrasonography or computed tomography). Six patients underwent surgical treatment of tuboovarian abscess within 48 hours of admission without an antibiotic trial and thus were excluded. The charts of the remaining 119 patients were retrospectively reviewed. Patients had been enrolled previously in treatment trials of acute pelvic inflammatory disease that were approved by the University of California, San Francisco, Committee on Human Research.

In all 119 patients either an initial clinical diagnosis of tuboovarian abscess was confirmed by ultrasonography with the exception of two patients who had computed tomography scan confirmation or ultrasonography after admission demonstrated a tuboovarian abscess in instances in which one had not been clinically appreciated. The ultrasonographic diagnosis of tuboovarian abscess required demonstration of a well-defined complex adnexal mass ≥4 cm in size with no apparently normal ipsilateral ovary. In the patients who required surgical intervention, all clinically and ultrasonographically diagnosed tuboovarian abscesses were confirmed at surgery. All masses were at least 4 cm in diameter and were complex in nature by imaging techniques.

Cultures were obtained in the majority of patients. Endocervical, endometrial, and abscess specimens were evaluated for *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. In addition, the endometrium and abscess were sampled for anaerobic and aerobic bacteria.

Cultures of the cervix for *N. gonorrhoeae* were obtained with a Dacron swab, inoculated directly onto modified Thayer-Martin agar plates, and held at 35° C in 5% carbon dioxide. Cervical specimens for *C. trachomatis* were collected with a sterile calcium alginate–tipped swab that was placed immediately in minimal essential media containing antibiotics and 10% fetal calf serum and refrigerated at 4° C until transport to the laboratory for isolation. Most specimens were processed within a few hours of acquisition, and all were processed within 24 hours.

A double-lumen, plastic telescoping catheter containing a wire brush and sealed with a gelatin plug was used for collection of the endometrial specimens. Endometrial brushes were divided into two parts under sterile conditions. One was processed for *C. trachomatis*, and the other for isolation of *N. gonorrhoeae* and other aerobic and anaerobic bacteria.

All specimens for *C. trachomatis* were inoculated onto monolayers of cycloheximide-treated McCoy cells by centrifugation. The cells were cultured for 65 hours, then examined for inclusions by either iodine or immunofluorescent staining. One blind passage was performed on all negative specimens.

Specimens were processed for isolation of facultative organisms by inoculation onto the following media, which were incubated with 5% carbon dioxide at 35° C: trypticase soy agar with 6% sheep blood, chocolate agar, calcium nutrient agar with 6% human blood, modified Thayer-Martin agar, and calcium nutrient agar with 6% sheep blood. Specimens processed for anaerobic growth were inoculated into *Brucella* agar supplemented with 6% sheep blood, vitamin K, and hemin, calcium nutrient agar with 6% sheep blood, kanamycin-vancomycin laked blood agar, and chopped meat carbohydrate broth incubated at 35° C in either a Gas-Pak jar (BBL, Cockeysville, Md.) or an anaerobic chamber (Coy Manufacturing, Ann Arbor).

N. gonorrhoeae and facultative bacteria were identified by standard methods. Anaerobic organisms were identified with gas-liquid chromatography and prereduced, anaerobically sterilized media.

Patients were placed in three groups according to antimicrobial treatment regimen (Table I). Group 1 consisted of 37 patients treated with a single-agent extended-spectrum antibiotic combined with doxycycline in most instances. Cefoxitin plus doxycycline (n = 27) was the most common regimen. Patients in group 2 (n = 64) were treated with clindamycin, usually in conjunction with an aminoglycoside with or without a penicillin. Patients in group 3 (n = 18) were initially treated with a group 1 regimen for 2 to 3 days and then were switched to a group 2 regimen. The decision to change antimicrobial agents was not due to treatment failure but rather was based on physician bias toward clindamycin-containing regimens when delayed ultrasonography revealed the presence of a tuboovarian abscess. The groups were compared with respect to clinical presentation, initial response to antibiotics, and treatment failure. Initial response was defined as defervescence, decreased pain, decrease in mass size, and discharge from hospital without need for surgical intervention. Early treatment failure was defined as lack of an initial clinical response plus institution of surgical intervention or a switch in antimicrobial therapy or both.

Table I. Antibiotic regimens used for treatment of tuboovarian abscesses

Group 1 (n = 37)	*Group 2 (n = 64)*	*Group 3 (n = 18)*
Cefoxitin and doxycycline (*n* = 27)	Clindamycin and tobramycin (*n* = 37)	Cefoxitin and doxycycline; clindamycin and aminoglycoside (*n* = 15)
Cefotetan and doxycycline (*n* = 5)	Clindamycin and gentamicin (*n* = 24)	Cefotetan and doxycycline; clindamycin and aminoglycoside (*n* = 2)
Ampicillin and sulbactam (*n* = 2)	Clindamycin and kanamycin (*n* = 1)	Ampicillin and sulbactam; clindamycin and aminoglycoside (*n* = 1)
SCH 34343 and doxycycline (*n* = 1)	Clindamycin and aztreonam (*n* = 1)	
Ciprofloxacillin (*n* = 2)	Clindamycin and ciprofloxacillin (*n* = 1)	

Table II. Clinical variables in patients with tuboovarian abscesses

	Group 1 (*n* = 37)	*Group 2* (*n* = 64)	*Group 3* (*n* = 18)	*Group 4* (*N* = 119)
Mean age (yr)	27.3 ± 7.4	28.0 ± 8.3	30.3 ± 7.2	27.7 ± 7.9
Parity	1.1 ± 1.3	0.85 ± 1.1	0.94 ± 1.1	0.98 ± 1.2
History of PID	20 (55.0%)	28 (43.7%)	7 (41.1%)	55 (46.0%)
Mean temperature (C)	38.3° ± 0.66°	38.2° ± 0.6°	38.6° ± 0.4°	38.3° ± 0.65°

Mean ESR (mm/hr)	63.5 ± 27.1	65.0 ± 28.9	66.5 ± 30.4	64.3 ± 28.0
Mean mass size (cm)	7.2 ± 2.2	6.7 ± 2.5	7.4 ± 2.0	6.9 ± 2.4
Days of intravenous antibiotics	7.8 ± 2.2	7.2 ± 2.3	9.4 ± 2.6	7.5 ± 2.3

PID, Pelvic inflammatory disease; *WBC,* white blood cell count; *ESR,* erythrocyte sedimentation rate.

Follow-up after discharge from hospital consisted of return visits at 2 weeks, with some follow-ups continuing >1 year after discharge. Clinical response at follow-up was defined as diminished or absent pelvic mass by pelvic examination or ultrasonography and diminished or absent pain. Late treatment failure was defined as a persistent mass or pain at follow-up. Seventy-five patients returned for follow-up.

Descriptive statistical analysis was used to compare the groups. Discrete variables were analyzed standard χ^2 test. Continuous variables were analyzed with the unpaired *t* test. A p value of <0.05 was considered statistically significant.

Results

There were no statistical differences among the three groups with regard to age, parity, and history of pelvic inflammatory disease (Table II). All patients were premenopausal and were aged 14 to 50, with a median of 27. The mean duration of hospital stay was 7.5 days, with a median stay of 7 days. There was no statistically significant difference in demographic characteristics among the groups (Table II).

Clinical data analysis revealed a mean temperature of 38.3° ± 0.6° C, a mean white blood cell count of 15.0 ± 9.0 × 10^6/ml and a mean sedimentation rate of 64.3 ± 28 mm/hr. There were no statistically significant differences among the treatment groups with regard to clinical presentation (Table II). Endometrial and cervical cultures done on admission demonstrated pathogens similar to those in our previously reported series.[4] Only 90 patients had both endocervical and upper genital tract microbiologic specimens obtained. *N. gonorrhoeae* was recovered from the endocervix in 49 patients (54.4%), and *C. trachomatis* was recovered in six patients (7%). From the endometrial cavity *N. gonorrhoeae* was recovered in 36 patients (40%), *C. trachomatis* from 6 patients (7%), and mixed anaerobic and aerobic bacteria from 68 patients (75%). The most common group of microorganisms recovered from the patients with tuboovarian abscesses included mixed anaerobic and facultative bacteria, predominantly *Bacteroides* sp., *Bacteroides bivius, Peptostreptococcus* sp., and *Gardnerella vaginalis.* Neither *C. trachomatis* nor *N. gonorrhoeae* were recovered from aspirates of the tuboovarian abscesses. There was no statistical difference with regard to pathogens among the groups.

Initial clinical response, defined as diminished pain, white blood cell count, or temperature, is summarized in Table III. In group 1, 31 of 37 patients (84%) responded to antimicrobial treatment and were discharged from the hospital without surgical intervention. An initial clinical response was observed in 45 of 64 patients (70%) in group 2 and in 14 of 18 patients (78%) in group 3. These differences were not statistically significant.

Overall, 90 of 119 patients (75%) initially responded to antibiotics alone. The remaining 29 (25%) under-

Table III. Initial clinical response to antibiotic therapy

	Successful response (N = 119) (No.)
Group 1	31/37 (84%)
Group 2	45/64 (70%)
Group 3	14/18 (78%)
TOTAL	90/119 (75%)

went surgical intervention because of early treatment failure. Of these, 17 (59%) underwent total abdominal hysterectomy with bilateral or unilateral salpingo-oophorectomy. Nine patients (31%) had unilateral adnexectomy and three (10%) had colpotomy drainage. All clinically and ultrasonographically diagnosed tuboovarian abscesses were confirmed in the 29 patients who underwent operation (Table IV). An additional 11 patients had late failure. Five patients underwent total abdominal hysterectomy and bilateral salpingo-oophorectomy >2 months after initial treatment. The remaining six patients had continued pelvic pain and masses but refused surgical intervention. The long-term clinical response rate with initial antibiotic therapy alone was 79 of 199 (66.5%).

Seventy-five patients underwent follow-up after discharge (Table V). Twenty-seven of 28 patients (96.4%) in group 1 had a diminished or absent pelvic mass on physical examination or follow-up ultrasonography. Twenty-five of 34 patients (73.5%) in group 2 and 12 of 13 patients (96.2%) in group 3 showed a clinical response at follow-up. On χ^2 analysis there was a statistically significant increase in follow-up response in group 1 patients compared with those in group 2 ($p = 0.036$). There were no statistical differences between groups 1 and 2 and groups 2 and 3.

Analysis of the influence of mass size on treatment response rates was similar among all three groups. In general, the trend indicated that the larger the mass, the greater the likelihood that the patient would not respond to antibiotics and would need surgery. This relationship increased dramatically in mass sizes >10 cm (Fig. 1).

Long-range follow-up (>1 year) was difficult to obtain in these patients. Of the patients available for long-term follow-up, 6 of 75 achieved an intrauterine pregnancy (4 in group 1, 2 in group 2, and 0 in group 3). The pregnancy rate of 8% is an underestimate because whether the patients were actively seeking pregnancy was not ascertained.

Comment

Management of acute unruptured tuboovarian abscesses remains controversial. Several authors have advocated prompt aggressive surgical treatment to decrease long-term morbidity and mortality.[6, 7] More recently, favorable results have been reported with conservative therapy consisting of broad-spectrum antibiotic treatment in an attempt to preserve reproductive potential.[1, 8, 9] Our study supports a conservative approach with an overall initial clinical response rate of approximately 75%. Only 25% of our patients needed surgical intervention after an adequate trial of broad-spectrum intravenous antibiotics during initial hospitalization. Most patients have an initial response within 72 hours of initially receiving antibiotics.[1] Over the long term an additional 11 patients (9.2%) were considered failures; this resulted in an overall success rate of 65.8%.

Numerous studies have now documented successful response rates in patients with tuboovarian abscess who are treated conservatively with antibiotics. However, there is a lack of data comparing the various regimens, particularly the newer second- and third-generation cephalosporins. Previous reports have suggested that improved response rates are achieved by using agents that penetrate abscesses and that are active against the resistant gram-negative anaerobes, such as *B. fragilis* and *B. bivius*. Cefoxitin and many of the third-generation cephalosporins and extended-spectrum penicillins fall into this category. In 1985 Hemsell et al.[10] reported a 95% initial success rate in using cefotaxime to treat 41 patients with tuboovarian abscesses. They did not, however, compare these results with a clindamycin- or metronidazole-containing regimen. In this study we found that cefoxitin in combination with doxycycline compared favorably with clindamycin-containing regimens in the treatment of tuboovarian abscesses. Group 3 reflected our preconceived notion that clindamycin was superior to cefoxitin and therefore that patients who were not immediately responding or who were discovered later to have a tuboovarian abscess were generally switched to a clindamycin-containing regimen. There were no striking differences whether clindamycin was added (group 3) or was not added (group 1), and the results of both groups compared favorably with those of the clindamycin-containing regimens. This study supports the efficacy of cefoxitin and similar advanced-spectrum cephalosporins in the treatment of tuboovarian abscesses. Changing antibiotic regimens in patients with pelvic inflammatory disease to a clindamycin- or metroidazole-containing regimen because a tuboovarian abscess is diagnosed does not appear to alter the outcome in the majority of cases.

Surgical intervention was required during the initial hospitalization in 29 of our patients (25%). A conservative approach with unilateral adnexectomy or colpotomy drainage was used in 11 (40%). None required

Group 3	12/13 (96.2%)

subsequent hysterectomy. Rivlin and Hunt[11] initially advocated this approach in 1977. In their report 57 patients in a series of 113 (50%) with tuboovarian abscess rupture underwent bilateral adnexal procedures and postoperative peritoneal lavage. Thus 50% of patients had management consisting of conservative surgical procedures.

This study emphasizes the importance of using imaging techniques to improve the quality of care in the management of tuboovarian abscesses. All patients included in the study had a mass ≥4 cm confirmed either ultrasonographically (98.3%) or by computed tomography scan (1.7%). All patients with a mass <4 cm determined either ultrasonographically or by physical examination were excluded from the study as a result of the difficulty in distinguishing a pyosalpinx from a tuboovarian abscess. Most important, all of these patients responded to medical management and did not need surgery. Fig. 1 shows the relationship between mass size and the success of medical therapy. These results emphasize the importance of mass size as determined by pelvic examination or ultrasonography or both. Follow-up of tuboovarian abscesses for increasing size also may indicate antibiotic treatment failure.

More conservative surgical treatments with laparoscopic drainage or unilateral adnexectomy or both have been advocated. Henry-Suchet et al.[12] reported 50 cases managed by laparoscopically directed drainage in 1984. Ninety percent (45 patients) had "complete initial clinical recovery"; 44 of the 45 had long-term follow-up. Twenty percent of those patients subsequently underwent total abdominal hysterectomy–bilateral salpingo-oophorectomy or unilateral adnexectomy. Thirteen percent had chronic pelvic pain, and 19% had bilateral tubal occlusion at follow-up laparoscopy. Twenty-eight percent had a normal pelvis on follow-up laparoscopy, and 11% had unilateral adnexal damage. Thus, at follow-up, 40% of patients had at least one patent tube.

Reich et al.[13] treated 21 women with tuboovarian abscesses with intravenous antibiotics and laparoscopic drainage. Twenty of the 21 had complete resolution. One underwent total abdominal hysterectomy and bilateral salpingo-oophorectomy. Six of the 20 subsequently achieved pregnancies. There were no laparoscopic injuries.

Computed tomography–guided drainage of intraabdominal abscesses is well documented.[14] Only recently have there been reports on computed tomography–guided drainage of tuboovarian abscesses. Worthen and Gunning[15] reported on 33 patients with computed tomography–guided or ultrasonographically guided percutaneous drainage of tuboovarian abscesses after 24 hours of intravenous antibiotics. The overall success rate was 77%. Complications occurred in two patients (6%); one had a bowel laceration and the other had rupture of the tuboovarian abscess. Tyrell et al.[16] had no complications in their series of eight patients. Seven of the eight had failure of conservative medical therapy (3 to 12 days of intravenous ampicillin, gentamicin, and clindamycin with little or no improvement), and one patient underwent emergency computed tomography–guided drainage after 24 hours of triple antibiotic therapy because of her critical condition. Seven of the eight (88%) had initial complete recovery and did not need surgery. Twenty months after treatment, one patient had recurrent symptoms that were presumed to have resulted from a new pelvic infection.

Although these studies of laparoscopic and percutaneous drainage are encouraging, there are still no randomized controlled studies comparing antibiotic treatment alone with antibiotics in combination with a drainage procedure. Moreover, these studies have not addressed the issues of long-term outcome, such as preservation of fertility. Additional studies are needed to prospectively evaluate the efficacy of new antibiotic regimens alone and in combination with laparoscopically or ultrasonographically guided drainage procedures. Until such data are available, conservative antimicrobial therapy is an appropriate initial approach in the management of a suspected tuboovarian abscess. The therapeutic regimen used must include an agent that is effective against β-lactamase–producing anaerobes, penetrates abscesses, and remains active within the abscess environment. As a result of our experience, three fourths of patients with tuboovarian abscess should respond to conservative medical therapy alone.

Discussion

DR. GLEN E. HAYDEN, Seattle, Washington. Drs. Reed, Landers, and Sweet are to be congratulated for an excellent study of the second- and third-generation antibiotics, especially the cephalosporins. The three major regimens are more formalized than those of the original 321 patients with tuboovarian abscess reported on in 1983.[1] The newer antibiotics meet the qualifications for penetration into the abscess cavity and remain active. Dr. Sweet has demonstrated that the tuboovarian abscesses resulted primarily from mixed anaerobic bacteria. The absence of the common sexually transmitted organisms is remarkable.

The conservative or initial medical approach is well supported by the successful data. The fact that 25% needed surgical intervention is important, but 40% of the surgical procedures were conservative. The clinical success rate of 75% with medical management is exceptional, but the cost factor for ≥7 days of hospitalization and 24-hour antibiotic therapy is staggering. The quoted cost ranges from $6,000 to $8,000; the unit cost to the patient of 6 or 12 hours is the same for all antibiotics. The newer antibiotics offer improved quality of treatment but as yet no reduction of cost.

As Dr. Sweeet has postulated, the ultimate aim of the treatment of tuboovarian abscess is the preservation of fertility and the prevention of pain or recurrent episodes. The need is for long-term randomized controlled studies of antibiotics versus antibiotics with conservative surgery.

There is sufficient evidence to support the idea of early ultrasonographically guided drainage or laparoscopic drainage of abscesses >10 cm. Adequate preantibiotic and postantibiotic therapies are essential. Operative laparoscopy is becoming more inventive with the development of jet stream dissection, irrigation, and suction of the abscess pocket. The three-way stopcock and 5 mm blunt suction device at the surgical level allow for repeated forceful irrigation and suction of an abscess site. The open laparoscopy approach is safe and useful in the more difficult abdomen.

Dr. Kenneth A. Burry, Portland, Oregon. This article describes the conservative treatment of a very difficult condition. I am interested in infertility and wonder if you have any long-term follow-up of fertility of these patients and the outcomes of their pregnancies.

Dr. Mary Martin, San Francisco, California. Dr. Sweet, please comment on the absence of the detection of *Chlamydia* in these cultures.

Dr. Carl Goetsch, Berkeley, California. I am old enough to have had personal experience in St. Louis with the treatment of this terrible disease without the aid of antibiotics. It was more harrowing than is suggested by the brief description by Dr. Sweet. Those patients took a very long time to arrive at a point where we felt it was safe to operate. We tried to provide supportive therapy until their temperatures had come down and had stabilized at a relatively low level or, as we would say, they had "cooled off." Then we would go in and evacuate the abscess. If it was accessible through the cul-de-sac, we did a colpotomy and put in a drain that we made on the spot from a 3/4-inch rubber tube. We cut it lengthwise and put two holes in it. We reached in with a clamp and pulled the "ears" out so that it made a very satisfactory T drain. If we could not drain the abscess through the cul-de-sac, we usually waited a long time. When we finally operated, even though occasionally the cyst would rupture, the result was very satisfactory. The patient would promptly become afebrile if she had had any low-grade fever. There was practically never any peritonitis, and we never got positive cultures from the purulent-appearing contents. The abscess had "burned out." When antibiotics came along (I was still in my training at that time), things began to look brighter for the treatment of this disease.

Dr. Sweet (Closing). Dr. Hayden, in the article I addressed the relative paucity of sexually transmitted disease organisms in the upper genital tract—the fallopian tubes, the abscesses, and the cul-de-sac. We actually found only one patient with gonococcus and none with chlamydia. I agree that the cost is extraordinary with these patients and would average >$8,000 for a week in the hospital. On the other hand, in our experience, patients who need surgery have 10 or 12 days of hospitalization at a much greater cost and greater risk of infertility. It is a dramatic change to be able to preserve fertility in the management of tuboovarian abscesses.

Dr. Hayden, I agree that we urgently need a randomized, controlled prospective study comparing modern conservative surgery to antibiotics alone versus the traditional surgical approach versus antibiotics alone. I hope that we do not find ourselves 5 or 10 years from now in a situation similar to that which we now have with the question of fetal monitoring, a situation in which it seems that we have an ethical problem to "go back" and do the appropriate study. There is no question that Henry-Suchet et al.,[1] Reich et al.,[2] and others have demonstrated good response with laparoscopic drainage. However, it is difficult to decide whether the cases they reported were all true tuboovarian abscesses.

Dr. Burry, we do have long-term data that I did not have time to present. In this study 8% of the 75 patients that we were able to follow up conceived within 1 year. In our initial study we had a 14% pregnancy rate after conservative medical therapy. This is not a great number, but it is better than zero, which is what you have if you do a hysterectomy and bilateral salpingo-oophorectomy. I think it is also important to recognize that the pregnancy rate is a minimum, because we do not ask the women whether they are trying to become pregnant. We feel it is an underestimate by 50%.

Dr. Martin, the absence of chlamydia in abscesses is consistent with what we have seen for a long time. In uncomplicated pelvic inflammatory disease, our chlamydia isolation rate has been about 15%, with a range from 10% to 25% over the last decade. However, we have never recovered *Chlamydia trachomatis* via monoclonal antibody stains, cultures, or even deoxyribonucleic acid probes, from the purulent material in a tuboovarian abscess. It is not clear whether the chlamydia organism is killed by an overgrowth of anaerobes, which we have postulated may happen with *N. gonorrhoeae*. The damage by Chlamydia is not from a purulent-type infection such as that associated with gonococcus but from the release of inflammatory mediators such as tumor necrosis factor and interferon, which produce tissue damage in the tubal epithelium.

Dr. Goetsch, you have succinctly and eloquently outlined for us the changes in management of tuboovarian abscesses. We have progressed a great deal since the preantibiotic era in preservation of fertility and hormonal function.

Antepartum testing in the hypertensive patient: When to begin

Richard A. Pircon, MD, David C. Lagrew, MD, Craig V. Towers, MD,
Wendy L. Dorchester, MS, Steve E. Gocke, MD, and Roger K. Freeman, MD
Milwaukee, Wisconsin, Orange and Long Beach, California

Antepartum testing has been recommended for patients whose pregnancies are complicated by hypertension. Although this is considered accepted practice, there are little data available to help the clinician know when to start testing. To help answer this question in patients with chronic hypertension and nonproteinuric pregnancy-induced hypertension, we reviewed the results of all antepartum tests between 1976 and 1987 in patients with these diagnoses. The primary mode of surveillance in the majority of our patients was the contraction stress test. We determined when patients first had positive contraction stress test results and when intervention occurred because of an abnormal antepartum test result. There were a total of 917 patients tested with these diagnoses. Fifty-three (5.8%) of these patients had at least one positive contraction stress test result. Twenty-two patients were delivered of infants before 35 weeks' gestation because of abnormal antepartum test results. Those with early intervention (<35 weeks' gestation) could not be differentiated from those with later intervention (≥35 weeks' gestation) by maternal age, diastolic blood pressure, or systolic blood pressure at the time of testing. The majority of patients who were delivered of infants before 35 weeks' gestation had a concomitant diagnosis of systemic lupus erythematosus, intrauterine growth retardation, diabetes mellitus, or superimposed preeclampsia. On the basis of when compromise was evident, patients with these diagnoses may require testing to be started as early as the fetus is considered viable. However, in those without these diagnoses, the clinician may delay the beginning of testing until 33 weeks' gestation without significant risk of pregnancy loss before testing. (AM J OBSTET GYNECOL 1991;164:1563-70.)

Key words: Antepartum fetal testing, hypertension, pregnancy-induced hypertension

Patients whose pregnancies are complicated by hypertension are at increased risk of intrauterine fetal death. In an attempt to prevent such an outcome, antepartum fetal surveillance has been advocated. Although it is accepted practice to initiate antepartum testing in these patients, there are limited data to suggest when testing should begin. Empirically, recent reviews have suggested starting testing anytime from 32 to 36 weeks' gestation unless the disease is poorly controlled or there is evidence of intrauterine growth retardation (IUGR).[1-3] In these clinical situations, it has been recommended that testing be started earlier.

In an attempt to better answer this question, we reviewed all antepartum fetal deaths and all antepartum fetal test results in pregnant patients with a diagnosis of chronic hypertension or nonproteinuric pregnancy-induced hypertension at the initiation of testing. Chronic hypertension was defined as hypertension diagnosed before pregnancy. Nonproteinuric pregnancy-induced hypertension was defined as hypertension first diagnosed during the studied pregnancy. With these data we will attempt to devise a scheme for timing the initiation of fetal testing in this patient population.

Material and methods

All patients tested at Memorial Womens Hospital, Long Beach, California, between January 1976 and December 1987 with a diagnosis of hypertension were evaluated for entrance in the study. Those with an isolated diagnosis of proteinuric pregnancy-induced hypertension (preeclampsia) were excluded from the study because it is generally accepted that these patients are at risk of uteroplacental insufficiency and should have testing started as soon as the disease process is apparent.[4] Patient history, antepartum fetal test results and pregnancy outcome were prospectively collected and retrospectively reviewed.

Recorded patient history included maternal age, gravidity, parity, gestational age when tested, testing method, result of test, systolic and diastolic blood pressures at the time of testing, gestational age at delivery, indication for delivery, other medical diagnoses, and birth weight. Small for gestational age (SGA) was defined as a neonate with a birth weight less than the 10th percentile for a given gestational age using California growth charts.[5] For purposes of this study, IUGR in-

cluded both those patients delivered of an SGA neonate and those patients who clinically demonstrated antepartum lag in fetal growth.

In the majority of patients, the primary mode of surveillance was a weekly contraction stress test. Testing procedures and test interpretation are described elsewhere.[6] Patients with multiple equivocal contraction stress test results or a contraindication to stress testing were followed with nonstress tests at frequent intervals. Tests were considered reactive if there were two accelerations that reached a peak of 15 beats per minute above the baseline and lasted 15 seconds in a 20-minute window of recording time. If the nonstress test result was nonreactive or if there was evidence of significant fetal heart rate deceleration on nonstress test, a contraction stress test or biophysical profile was performed. Biophysical profiles were performed and interpreted as outlined by Manning et al.[7] except for interpretation of amniotic fluid volume. In this study, the minimal acceptable amniotic fluid volume was a 2 cm vertical pocket free of extremities and umbilical cord. Intervention because of an abnormal test result was dependent on the specific clinical situation and was the decision of the primary care physician often in consultation with the perinatal staff. Indications for intervention were prospectively recorded. All test interpretations were performed and recorded prospectively. Each contraction stress test and nonstress test was read by at least two perinatal staff physicians.

If the antepartum fetal test is to be effective, it must begin before significant fetal compromise has begun. For this reason, the following three occurrences were used to represent evidence of fetal compromise: (1) gestational age at intrauterine fetal death; (2) gestational age at the first positive contraction stress test result; and (3) gestational age when intervention occurred because of abnormal antepartum fetal test result.

Patients with such evidence of compromise were compared to those without such evidence for maternal age, gravidity, parity, other associated medical illnesses, systolic and diastolic blood pressure levels at the time of testing, and birth weight. Comparisons were made using the Student t test, one-tail Fisher exact test, χ^2 with Yates correction. All variances expressed are plus or minus 1 SD.

Results

Antepartum fetal tests were performed on 8189 high-risk obstetric patients during the years studied. Of those tested, 408 had a diagnosis of chronic hypertension and 509 had a diagnosis of nonproteinuric pregnancy-induced hypertension at the initiation of testing. The mean maternal age, gravidity, and parity were 29.1, 2.6, and 0.9, respectively.

During the study period there were 10 stillbirths that occurred among all hypertensive patients admitted to Women's Hospital. A list of these cases is shown in Table I. It should be noted that nine of the 10 patients were not among the antepartum fetal test study population because they presented with fetal deaths and never had fetal testing. The earliest stillbirth occurred at 21 weeks' gestation. This patient had a concomitant diagnosis of diabetes mellitus. The next earlier stillbirth also occurred in a patient with diabetes who was 26 weeks' gestation at the time of death. It is of interest that both of these patients were delivered of fetuses with true knots in the umbilical cord. Five of the stillbirths occurred in patients with superimposed preeclampsia. None of the fetuses had congenital anomalies. Only one patient had testing initiated before the intrauterine death, and that patient's last test was a reactive nonstress test fewer than 7 days before the fetal death.

There were five neonatal deaths among the 917 patients tested (Table II). Three of them were attributed to respiratory distress syndrome, one of which also had

Table II. Neonatal deaths in patients with chronic hypertension or nonproteinuric pregnancy-induced hypertension

Patient	*GA (wk)*	*Weight (gm)*	*SGA*	*Labor and delivery*	*Apgar scores*	*Neonatal diagnosis*
1	26	420	Yes	SPROM, CS (fetal distress), renal failure	4-9	RDS
2	28	850	No	CS (maternal indications), BP 190/120	5-8	RDS
3	33	1450	Yes	Twin, PTL, CS (fetal distress)	0-2	RDS, MAS
4	33	1760	Yes	SPROM, CS (breech)	1-5	RDS, Trisomy 13
5	39	3710	No	NSVD	8-9	Anomalies

GA, Gestational age; *weight,* birth weight; *SPROM,* spontaneous premature rupture of membranes; *CS,* cesarean section; *RDS,* respiratory distress syndrome; *PTL,* premature labor; *MAS,* meconium aspiration syndrome; *NSVD,* normal spontaneous vaginal delivery; *BP,* blood pressure.

meconium aspiration syndrome. The other two were attributed to anomalies. One of the deaths secondary to respiratory distress syndrome occurred in an infant delivered at 28 weeks' gestation because of severe maternal disease (blood pressure, 190/120). However, none of the neonatal deaths occurred after intervention for abnormal antepartum fetal test results. Thus there were a total of six perinatal deaths in those patients who underwent antepartum fetal tests, giving an uncorrected perinatal mortality rate of 6.5/1000.

Of the 917 patients tested, 53 (5.7%) had at least one positive contraction stress test result. Of the 53 patients with a positive test result, 23 (43%) occurred before 35 weeks' gestation. The cumulative percentage of positive contraction stress test results that occurred at or before a given gestational age is shown in Fig. 1. The first positive test results occurred at 26 weeks' gestation.

Similar results were found when examining the data of those patients delivered of infants because of an abnormal test result. A total of 119 (13.0%) patients were delivered of infants because of an abnormal test result. Twenty-two (19%) of these patients were delivered of infants before 35 weeks' gestation. Of those who required intervention, the cumulative percentage of interventions that occurred at or before a given gestational age is shown in Fig. 2. The earliest a patient was delivered of an infant because of an abnormal antepartum test result was 26 weeks' gestation.

Comparisons were made in an attempt to identify those patients whose contraction stress test result were positive before 35 weeks' gestation or who had intervention before 35 weeks' gestation because of an abnormal test result. Patients with antepartum fetal test evidence of early compromise could not be identified by maternal age or diastolic or systolic blood pressure levels at the time of testing.

There were 114 patients who were delivered of SGA infants. This included 55 patients with chronic hypertension and 59 patients with nonproteinuric pregnancy-induced hypertension. Fourteen of the 53 patients

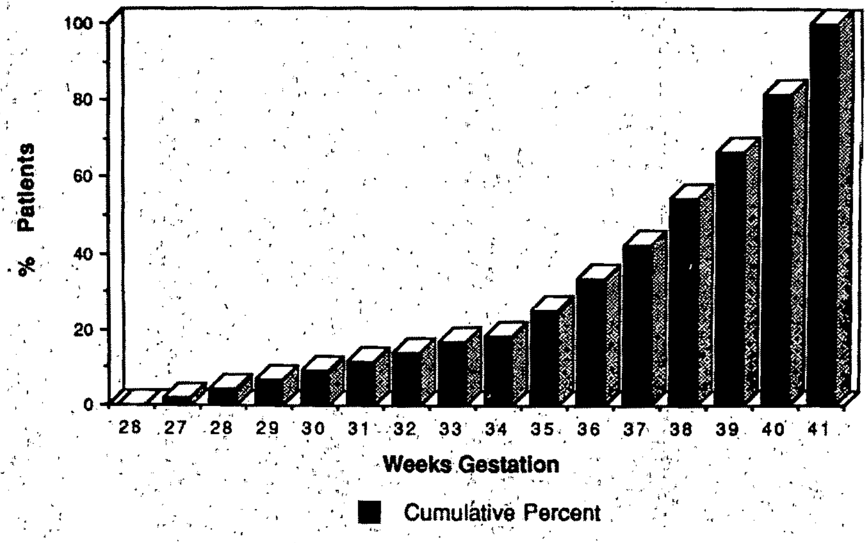

Fig. 2. Cumulative percentage of all patients who required delivery because of abnormal antepartum test results by gestational age when delivery occurred.

(26%) with a positive contraction stress test result and 29 of the 119 patients (24%) delivered of infants because of abnormal test results had SGA infants. The mean birth weight percentiles of the various groups are shown in Tables III A, III B, and III C. There was no statistical difference in birth weight percentile between those study patients tested for hypertension and those tested for all other reasons during the study interval. However, among hypertensive patients, those patients who had abnormal test results early in pregnancy (<35 weeks' gestation) had lower mean birth weight percentiles than those who first had abnormal test results at or after 35 weeks' gestation (Table III B and III C).

Of the 22 patients who required intervention for abnormal antepartum test results before 35 weeks' gestation, 15 (68%) had IUGR and eight (36%) had superimposed preeclampsia. Only five (22%) with intervention for abnormal antepartum test results before 35 weeks' gestation had neither IUGR nor superimposed preeclampsia.

Patients with positive contraction stress test results and intervention because of abnormal test results were further reviewed with respect to coexistent medical diagnoses. Of the 53 hypertensive patients with a positive contraction stress test result, 12 had a diagnosis of diabetes mellitus. This included four patients with class A diabetes. There was no statistically significant difference in the incidence of a positive contraction stress test result in diabetic patients when compared with nondiabetic patients (8.9% vs 5.3%). However, when a diabetic patient had a positive contraction stress test result it occurred at a gestational age of <35 weeks with greater frequency than in those patients without diabetes (Fig. 3). A similar trend was seen when reviewing those patients with intervention because of abnormal antepartum test results (Fig. 3). However, this difference did not reach statistical significance. Similar results were seen when reviewing patients with a concomitant diagnosis of systemic lupus erythematosus (Fig. 4). The earliest gestational age at which intervention occurred as a result of abnormal test results in patients with diabetes or systemic lupus erythematosus was 28 and 26 weeks' gestation, respectively.

Those patients with evidence of early compromise (a positive contraction stress test result or intervention because of an abnormal antepartum fetal test result at <35 weeks' gestation) were then evaluated for evidence of IUGR or a concomitant diagnosis of diabetes mellitus or systemic lupus erythematosus. Of the 23 patients who had positive contraction stress test results before 35 weeks' gestation, only three patients did not have one of these three diagnoses. Similarly, only three of 22 patients with early intervention (<35 weeks' gestation) did not have one of these three risk factors. One of three remaining patients had superimposed preeclampsia. Patients who required intervention because of an abnormal antepartum test result without IUGR, systemic lupus erythematosus, or diabetes were then studied. The cumulative percentage of patients without IUGR, systemic lupus erythematosus, or diabetes who required intervention at or before a given gestational age is shown in Fig. 5.

Comment

It has been long recognized that patients with hypertensive disease are at risk of intrauterine fetal death. For this reason, antepartum fetal heart rate testing or biophysical profile testing has generally been recom-

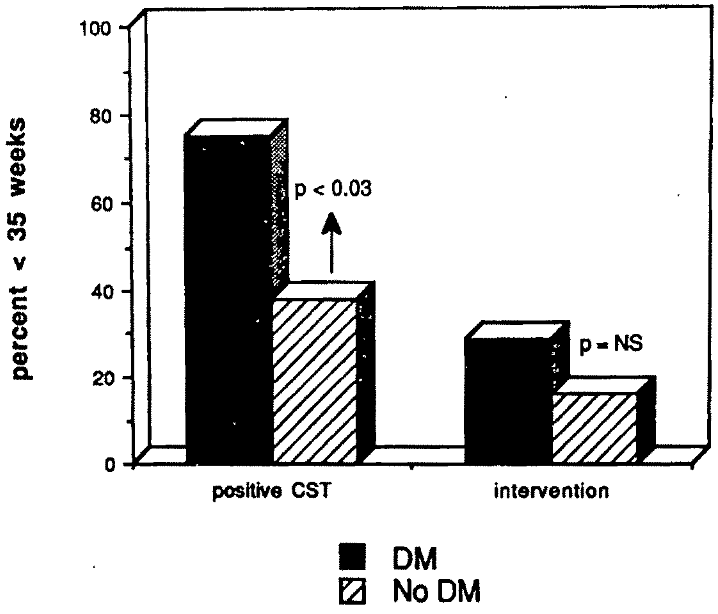

Fig. 3. Percentage of hypertensive patients with diabetes compared with those without diabetes who had either positive test results before 35 weeks' gestation or required intervention before 35 weeks' gestation.

mended in these patients.[8,9] Indeed, in this study there was only one fetal death among all 917 hypertensive patients in the group with antepartum fetal tests, whereas there were nine among hypertensive patients who did not have fetal testing during the same time interval. Although there have been considerable data to support the benefits of these testing methods, there are little data to guide the clinician as to when to start testing.

Ideally testing should be initiated before evidence of fetal compromise. The onset of compromise is variable and dependent on the clinical situation. Most reports have recommended that testing be started between 32 and 36 weeks' gestation.[1-3] However, there are patients who show evidence of compromise before this gestational age. In an attempt to identify those patients who demonstrate compromise earlier in pregnancy, we examined pregnancy outcomes and antepartum test results in patients with a primary diagnosis of chronic hypertension or nonproteinuric pregnancy-induced hypertension. We defined compromise as stillbirth, positive contraction stress test result, or intervention because of any abnormal antepartum test result (contraction stress test, nonstress test, biophysical profile). A significant percentage of patients had at least one positive contraction stress test result (5.3%) or intervention because of an abnormal test result (13.0%). Forty-three percent of those with a positive contraction stress test result had their first positive test result before 35 weeks' gestation and 18% of those who required intervention because of an abnormal test result did so

Table III A. Birth weight by percentile

	Weeks' gestation	*Mean weight percentile*	*p Value*
All patients	>25	51.3 ± 25.8	
Chronic hypertension	>25	53.0 ± 25.7	NS
Nonproteinuric PIH	>25	49.8 ± 26.8	NS

PIH, Pregnancy-induced hypertension.

Table III B. Birth weight by percentile for patients with positive contraction stress test results

	Weeks' gestation	*Mean weight percentile*	*p Value*
Chronic hypertension	<35	14.3 ± 6.4	<0.001
Chronic hypertension	≥35	50.3 ± 27.8	
Nonproteinuric PIH	<35	17.9 ± 4.8	<0.001
Nonproteinuric PIH	≥35	47.5 ± 23.7	

PIH, Pregnancy-induced hypertension.

Table III C. Birth weight by percentile for patients with intervention because of abnormal test results

	Weeks' gestation	*Mean weight percentile*	*p Value*
Chronic hypertension	<35	14.6 ± 6.9	<0.001
Chronic hypertension	≥35	51.3 ± 25.0	
Nonproteinuric PIH	<35	9.6 ± 9.3	<0.001
Nonproteinuric PIH	≥35	60.3 ± 22.4

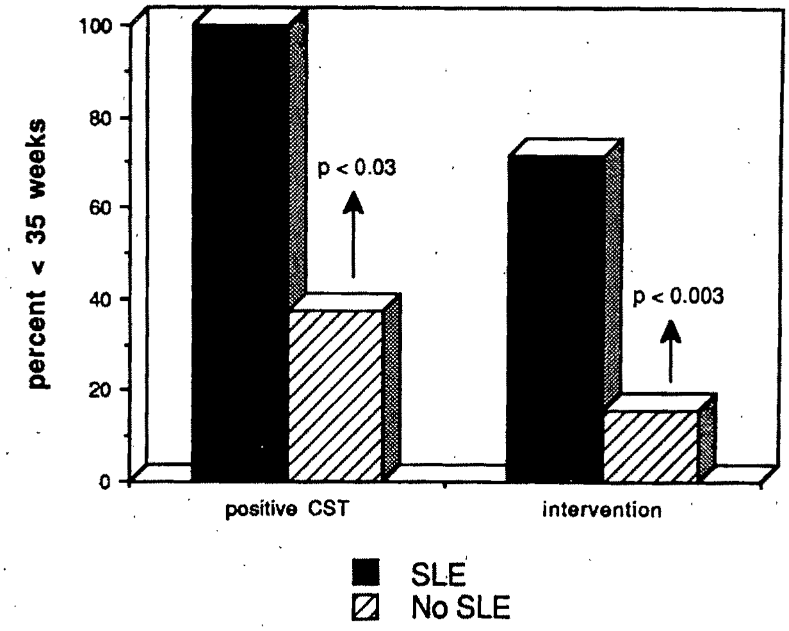

Fig. 4. Percentage of hypertensive patients with systemic lupus erythematosus compared with those without systemic lupus erythematosus who had either positive test results before 35 weeks' gestation or required intervention before 35 weeks' gestation.

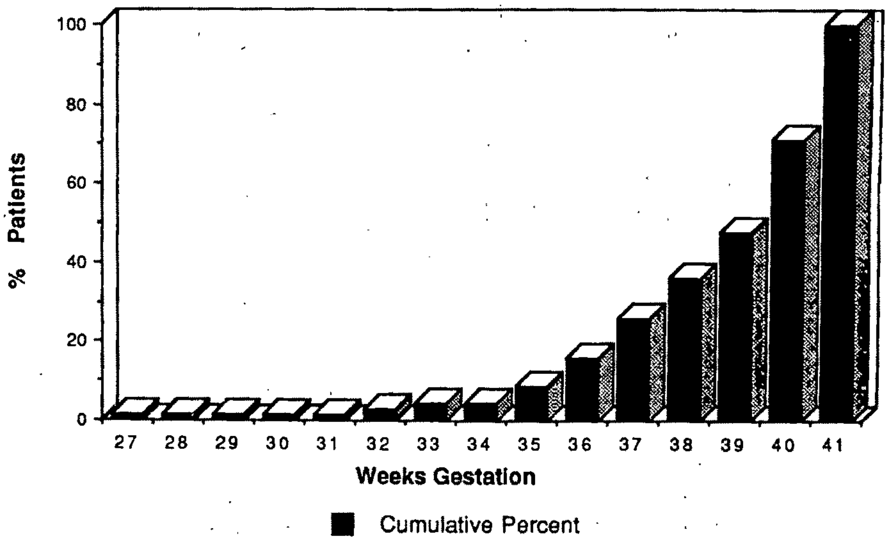

Fig. 5. Cumulative percentage of all hypertensive patients without IUGR, systemic lupus erythematosus, or diabetes who required delivery because of abnormal antepartum test results by gestational age when delivery occurred.

before 35 weeks' gestation. Therefore we cannot support the recommendation that testing be started at 35 weeks' gestation in all patients with a diagnosis of chronic hypertension or nonproteinuric pregnancy-induced hypertension.

Recognizing this problem, recent reviews have suggested that testing be started earlier in patients with risk factors such as poorly controlled blood pressure.[1-3] This recommendation cannot be substantiated by our data. There was no correlation between those who demonstrated compromise before 35 weeks' gestation and the systolic or diastolic blood pressure level at the time of testing. Furthermore maternal age did not correlate with the onset of fetal compromise.

Another suggestion has included earlier testing in those patients with evidence of IUG or superimposed preeclampsia. Although a substantial number of patients with early compromise were delivered of a growth-retarded neonate, approximately one third of patients with evidence of early compromise were delivered of a normally grown infant. Similarly, superimposed preeclampsia was not evident in all patients with early compromise.

In patients with chronic hypertension or nonproteinuric pregnancy-induced hypertension, diabetes or systemic lupus erythematosus appear to place the patient at additional risk of early compromise in pregnancy. These patients demonstrated compromise before 35 weeks' gestation with greater frequency when compared with those without these diagnoses. When coupled with evidence of IUGR and superimposed preeclampsia these factors identified more than 90% (20/22) of patients who required early intervention because of abnormal test results.

Patients with evidence of IUGR and patients with systemic lupus erythematosus required delivery because of abnormal antepartum test results as early as 26 weeks' gestation. Therefore in patients with hypertension, an obstetric ultrasonographic examination for interval growth at approximately 26 weeks' gestation would be helpful to identify the growth-retarded fetus. Testing in patients with evidence of growth retardation as well as in patients with systemic lupus erythematosus needs to be started when fetal viability is sufficient to consider intervention (as early as 25 to 26 weeks' gestation in our hospital). Similarly the earliest intervention in a hypertensive patient with diabetes was 28 weeks' gestation. Two patients with diabetes and hypertension had stillbirths in the late phase of the second trimester. Therefore testing should be started at viability in this patient population as well.

If patients with IUGR, systemic lupus erythematosus, and diabetes are excluded, the cumulative percentage of patients who required intervention because of abnormal test results at or before a given gestational age is shown in Fig. 5. One can see that there are only a few patients who demonstrate early compromise (<35 weeks' gestation) without the noted risk factors. Furthermore, if one reviews those patients with an intrauterine fetal death who had no testing and excludes those with diabetes and IUGR, then all the remaining patients experienced the loss after 33 weeks' gestation. Therefore we recommend to start testing at 33 weeks' gestation in those patients with chronic hypertension or nonproteinuric pregnancy-induced hypertension but without systemic lupus erythematosus, IUGR, diabetes, or superimposed preeclampsia. Whereas this recommendation will inevitably miss a rare patient with earlier compromise, early testing will be avoided in the majority of patients with chronic hypertension or nonproteinuric pregnancy-induced hypertension.

Discussion

DR. MALCOLM MARGOLIN, Los Angeles, California. It is well known that patients with hypertensive disease are at risk of intrauterine fetal death.[1] Historically two thirds of fetal deaths occur before the onset of labor.[2] To reduce this risk, fetal surveillance must begin before this time. The goal of such surveillance is the detection of potential fetal compromise so that measures may be taken to prevent adverse fetal outcome.[3] The literature is replete with reports documenting the benefit of antepartum fetal testing in reducing the stillborn rate in the high-risk pregnancy.[1, 2] However, there is no universally agreed on time at which such surveillance should begin.

Drs. Pircon, Freeman et al. have reviewed a group of pregnant patients with chronic hypertension and nonproteinuric pregnancy-induced hypertension who presented over a 12-year period. There were 10 patients with stillborn fetuses included in the study. Nine of these patients did not have antepartum fetal testing because they first presented with fetal death. There were 917 patients who had antepartum fetal testing. Of these patients there was only one stillborn fetus and this occurred in a patient with superimposed preeclampsia. In the entire study group there was only one patient who had a stillborn fetus and who had no additional risk factor aside from hypertension.

A total of 119 patients were delivered of infants because of abnormal antepartum test results. Of these 119 patients, 22 were delivered of infants before 35 weeks' gestation. Most of these patients had a concomitant diagnosis of systemic lupus erythematosus, IUGR, diabetes mellitus, or preeclampsia.

The authors reviewed patients in various subgroups in an attempt to identify the time when antepartum testing in these high-risk patients should be initiated. They found that if tests were initiated at 35 weeks' gestation they would miss 18% of patients requiring intervention because of an abnormal test result. However, if all patients had testing initiated at 26 weeks' gestation (viability) a large number of unnecessary tests at significant financial and manpower costs would be required. For example, the costs of these tests at my hospital are as follows: nonstress test, $50; contraction stress test, $80; and biophysical profile, $200. On further analysis of their patient groups they found that if they began testing at 33 weeks' gestation in patients with hypertension or nonproteinuric pregnancy-induced hypertension only (i.e., patients without other concomitant diagnosis), they would identify the vast majority of patients who would require early intervention. They then defined additional subgroups of high-risk patients who require earlier testing, these being hypertensive patients with a concomitant diagnosis of systemic lupus erythematosus, IUGR, diabetes mellitus, or superimposed preeclampsia. Their recommendation is for testing to begin at fetal viability (i.e., 26 weeks' gestation) in patients with these diagnoses but for all other testing to begin at 33 weeks' gestation.

It is reemphasized by the findings in this article that it is essential for hypertensive pregnant patients to have glucose screening, an ultrasonographic examination at 26 weeks' gestation to rule out IUGR, and an evaluation to rule out the presence of collagen vascular disorders.

I want to congratulate the authors on their continued fine work in the area of attempting to define the parameters of antepartum fetal surveillance. In this age of cost containment it is essential to limit unnecessary testing while remaining cognizant of patients at reasonable risk of increased perinatal mortality. If all patients in this study had testing started at 26 rather than 33 weeks' gestation there would have been an average of seven more tests required per patient or a total of 6419 additional tests required at the very least. At an average cost of $80 per test there would be a differential of $513,520 which is surely significant. However, because many of the patients in this study had concomitant diagnoses that required earlier testing, the savings might not have been so significant. I would like to ask the authors how many of the 917 hypertensive patients studied had concomitant diagnoses that by their recommendations would have required earlier testing? If we review those patients with stillborn fetuses we find that only one patient did not have an additional risk factor.

Because antepartum death is not the only end point in which we are interested, I would also like to know what the perinatal mortality was in this group of patients. Of particular interest would be the outcome of the 119 patients who underwent early delivery because of abnormal antepartum fetal test results and how the outcome of those delivered of infants before 35 weeks' gestation compared with those delivered of infants after that time.

5. Pircon RA, Freeman RK. The contraction stress test. Obstet Gynecol Clin North Am 1990;17:129-46.

DR. HOWARD A. BLANCHETTE, Berkeley, California. Dr. Freeman, you are the father of the contraction stress test. What is the role of the nonstress test in the evaluation of these patients?

DR. E. PAUL KIRK, Portland, Oregon. In the list of stillbirths, it seemed that there was a high average maternal age with the exception of one 16-year-old patient. The latter is a little bit surprising. Might maternal age be a variable in the group of patients without other complications that might lead you to adjust the recommendations for starting antepartum testing?

DR. FREEMAN (Closing). Dr. Margolin, the numbers of patients with various complications who would have required testing before 32 weeks' gestation were: 145 with diabetes, 114 with IUGR, and 11 with lupus erythematosus. The time of onset of superimposed preeclampsia was quite variable and usually occurred just about the time of intervention, so I do not know what costs a policy of earlier testing would have added.

The overall uncorrected perinatal mortality was 6.5/1000: one stillbirth and five neonatal deaths. Analysis of the neonatal deaths revealed that none were a result of intervention because of an abnormal antepartum fetal test result. Two were caused by anomalies, two followed premature deliveries for other indications, and one resulted from premature delivery for maternal indications.

Dr. Blanchette, I am always happy to talk about contraction stress tests and nonstress tests. We do not use a contraction stress test any more for primary surveillance. We use a modified biophysical profile, which consists of nonstress test and an amniotic fluid index. We do that on a twice-weekly basis. We have used the modified biophysical profile for the past 2 years for primary fetal surveillance. We had no fetal deaths with that approach. I think the reason that the modified biophysical profile is better than the nonstress test alone is because the nonstress test alone is only an acute monitor. The modified biophysical profile with the use of the amniotic fluid volume contains a chronic marker as well. The one place where we do not use that approach is in diabetic patients; we still use the contraction stress test because the amniotic fluid volume of diabetic patients is not an accurate marker. Diabetic fetuses can die with normal amniotic fluid volume.

Dr. Kirk, my coauthor Dr. Pircon looked at the maternal age along with a number of other factors and was unable to find a correlation between maternal age, positive contraction stress test results, or the need for intervention. Maternal age correlated with stillbirths, but primarily in nontested patients. Maybe that says that there is a group of older patients who do not get tested for some reason.

The roles of ultrasonography and amniocentesis in evaluation of elevated maternal serum α-fetoprotein

Karen K. Lindfors, MD,[a] David P. Gorczyca, MD,[a] Frederick W. Hanson, MD,[b] Frances R. Tennant, PhD,[b] John P. McGahan, MD,[a] and Ann G. Peterson, MN[b]
Sacramento, California

A total of 681 pregnant women were referred for evaluation of elevated maternal serum α-fetoprotein levels. Ultrasonographic examination yielded an explanation for the elevation of maternal serum α-fetoprotein in 42% of patients. Diagnoses made by ultrasonography included incorrect fetal dating, multiple gestation, fetal death, open neural tube defect, abdominal wall defect, placental abnormalities, cystic hygroma, renal anomalies, and oligohydramnios. Optimal prenatal diagnosis of fetal anomalies also requires the use of amniocentesis in many patients. Amniocentesis may be obviated if fetal dating is incorrect, if an unsuspected multiple gestation is discovered, or if there is a clear anomaly and the parents do not desire genetic counseling based on karyotype information. If the fetus appears normal, the ultrasonographic results are equivocal, or the parents desire more detailed genetic counseling when an anomaly is found by ultrasonography, then amniocentesis should be performed. Thirteen abnormalities were diagnosed by amniocentesis alone in this group. (AM J OBSTET GYNECOL 1991;164:1571-6.)

Key words: Maternal serum α-fetoprotein, amniocentesis, fetal ultrasonography

The California Maternal Serum α-Fetoprotein Screening Program offers prenatal testing aimed at detection of open neural tube defects and other congenital anomalies. The program began in 1986 in response to legislation that required all pregnant women be offered maternal serum α-fetoprotein (AFP) testing between 15 to 20 weeks' gestation. Women with abnormal maternal serum AFP levels are referred to state-approved prenatal diagnostic centers for counseling, ultrasonography, and possible amniocentesis by persons with known expertise in these areas.

Ultrasonography plays a vital role in the evaluation of patients with elevated maternal serum AFP levels. Such elevations can be a result of open neural tube defects, but they can also be caused by incorrect fetal age, multiple gestation, fetal death, abdominal wall defects, cystic hygroma, renal anomalies, intestinal atresias, and other anomalies.[1, 2] Most of these conditions can be identified ultrasonographically.

This article reviews the roles of ultrasonography and amniocentesis in the evaluation of patients with elevated maternal serum AFP levels at our center.

Material and methods

During the period from April 1986 through December 1989, 681 pregnant patients were referred for early midtrimester ultrasonography and possible amniocentesis because of elevated maternal serum AFP levels. All maternal serum AFP testing was performed during 15 through 20 weeks' gestation, as determined by the patient's last menstrual period. An elevated maternal serum AFP level was defined by the State of California as one that exceeded 2.5 multiples of the median (MOM) for menstrual age for singleton pregnancies. For known twin gestations an elevated maternal serum AFP level was defined as one that exceeded 3.5 MOM before February 12, 1987, and one that exceeded 4.5 MOM after that date. The median maternal serum AFP level is determined by certified laboratories of the State of California.

Accurate fetal age was determined by biparietal diameter or femur length in all cases. The number of gestations was also determined ultrasonographically. If the maternal serum AFP level was within normal range after correction for ultrasonographically determined fetal age and number of gestations or if the fetal age was too advanced for inclusion in the program, a full obstetric ultrasonographic examination was performed. If the maternal serum AFP level was truly elevated after correction, a detailed ultrasonographic examination and/or amniocentesis was performed. These sonograms were performed by sonologists experienced in fetal ultrasonography. Fetal anatomy was examined in detail. Measurements for fetal evaluation and fetal dating were obtained; these included biparietal diameter,

Table I. Ultrasonograhic diagnoses in patients referred for elevated maternal serum AFP*

Diagnosis	*No. of patients (n = 681)*	*% of Total patients*
Incorrect fetal age	120	18
Multiple gestation	64	9
Fetal death	33	5
Open neural tube defect	31	5
Abdominal wall defect	20	3
Oligohydramnios	22	3
Placental abnormalities	21	3
Cystic hygroma	4	0.5
Renal anomalies	2	0.3
Cystic adenomatoid malformation	2	0.3
Cerebral ventriculomegaly	1	0.1
Agenesis of the corpus callosum	1	0.1
Normal	373	55

*Patients may have more than one diagnosis.

head circumference, abdominal circumference, and femur length. Fetal position, amniotic fluid volume, and placental position and structure were also noted.

Full fetal ultrasonographic examinations were performed with a variety of real-time scanners during the first 6 months of the screening program. After this initial period, detailed examinations were performed only on an Acuson 128 scanner (Mountain View, Calif.) with transducer frequencies from 3.0 to 5.0 MHz.

In cases in which the fetal sonogram showed an anomaly to account for the elevated maternal serum AFP level, amniocentesis was performed if the anomaly was associated with chromosomal aberrations or if the patient desired such information for use in genetic counseling for consideration of future pregnancies. In consenting patients, amniocentesis was always attempted if the fetus appeared normal ultrasonographically or if the ultrasonographic results were equivocal.

The amniotic fluid AFP level was determined by our laboratory. If this level exceeded 2.0 MOM for menstrual age, samples were sent to an independent laboratory (University of California, Los Angeles Medical Center) for repeat amniotic fluid AFP analysis and for determination of the presence of acetylcholinesterase. This protocol was mandated by the State of California. Amniotic fluid AFP levels more than 2.0 MOM were considered elevated. Acetylcholinesterase was reported as not present, weakly positive, or strongly positive.

All patients were counseled with regard to the significance of ultrasonographic findings and amniocentesis results. Therapeutic options were offered. If the pregnancy was terminated, fetal pathologic findings were correlated with the results of ultrasonography and amniocentesis. If the pregnancy was continued, information on the outcome was obtained from the referring physician and was correlated with prenatal tests.

Results

Ultrasonographic results. Six hundred and eighty-one patients with elevated maternal serum AFP levels had ultrasonography with more detailed sonograms performed in 520 patients. A total of 137 ultrasonographic abnormalities were detected (Table I).

There were seven fetal anomalies diagnosed in 64 twin pregnancies. Open spina bifida was detected ultrasonographically in one twin of a diamniotic-dichorionic pregnancy. Two other sets of twins had one fetus affected with an abdominal wall defect, one omphalocele and one gastroschisis. One set of twins had both twins affected with gastroschisis, which has been previously reported.[3] There was one set of twins with one live twin and one dead twin and in one set of twins, one twin was affected with crossed-fused renal ectopia.

In the group of 33 patients with fetal death there were eight patients who had additional related diagnoses seen by sonogram: three cases of oligohydramnios, one cerebral ventriculomegaly, and one encephalocele, one live co-twin, one abruptio placentae, and one cystic hygroma.

Twenty-nine diagnoses of open neural tube defects were made by ultrasonography. They were 17 anencephalic fetuses, four with encephalocele, and eight with open spina bifida. In two additional patients, the sonograms were equivocal for the diagnosis of open spina bifida.

Twenty abdominal wall defects were diagnosed by ultrasonography in the referred patients. Ten were gastroschisis, eight were omphaloceles, one was an omphalocele with other anomalies, and one was a limb-body wall complex.

In the 22 cases of oligohydramnios there were three fetal deaths and one fetus had an omphalocele. In the remainder of cases the examination by ultrasonography was limited but no definite anomalies were seen.

Among those 21 patients with placental abnormalities seven had placenta previa, seven had abruptio placentae, four had venous lakes, and three had subchorionic hematomas.

Other anomalies diagnosed by ultrasonography in this series are listed in Table I.

Amniocentesis results. Amniocentesis was performed on 442 (65%) patients. It was not offered to those patients whose maternal serum AFP level fell within normal range when corrected for fetal age or multiple gestation or whose dates were too far advanced for elective options ($n = 161$). Amniocentesis failed in seven patients with oligohydramnios. The procedure was refused by the remaining 71 patients.

Among the 442 patients who underwent amniocentesis, 13 additional confirmed abnormalities were diagnosed (Table II).

Nine chromosomal anomalies occurred in this series. Four of these occurred in conjunction with other ultrasonographically diagnosed abnormalities. One XO

(Turner's syndrome) karyotype was detected in a fetal death. Two of the fetuses with encephaloceles had chromosomal aberrations: one unbalanced 21/21 translocation and one trisomy 18. One fetus with an abdominal wall defect had a trisomy 18.

Five chromosomal anomalies occurred in patients with normal sonograms. There were three significant (47, XYY; mosaic XO; 46,X + centromeric fragment) and two were minor (familial inversion, 46,X with inverted Y).

Also among patients with normal sonograms there were three cases in which the amniotic fluid AFP was significantly elevated and the acetylcholinesterase was strongly positive; all three had open spina bifida confirmed after elective abortion.

Amniocentesis results were abnormal in five other patients with normal sonograms; in all five cases the fetuses were normal. In four of these cases the amniotic fluid AFP levels were mildly elevated (less than 3 MOM) and the acetylcholinesterase results were negative; these pregnancies were continued with normal outcomes. In the fifth case the amniotic fluid AFP was markedly elevated (20 MOM) and the acetylcholinesterase level was weakly positive but the fluid had been slightly bloody. Although the patient was advised to undergo repeat amniocentesis, she elected to terminate the pregnancy and a normal fetus was seen on pathologic examination.

In the remaining 424 patients who underwent both amniocentesis and ultrasonography there was appropriate correlation between the two tests. Nineteen of the ultrasonographically detected open neural tube defects were confirmed by amniocentesis; all were strongly positive for acetylcholinesterase and had significantly elevated amniotic fluid AFP levels. Ten cases of anencephaly did not undergo amniocentesis. In two cases in which the ultrasonographic diagnosis of open spina bifida had been equivocal, amniocentesis results were normal and outcomes were normal.

Twelve patients with fetuses with abdominal wall defects underwent amniocentesis. In all, the acetylcholinesterase level was at least weakly positive and amniotic fluid AFP level was elevated.

In the case of multicystic dysplastic kidney, the amniotic fluid AFP level was elevated but the acetylcholinesterase results were negative.

Outcome. Information on the outcome of pregnancy was obtained in 452 (87%) of the patients with maternal serum AFP levels that were persistently elevated after correction for fetal age and number of gestations. Sixty-eight patients were lost to follow-up; 59 of these had normal sonograms, four had oligohydramnios, two had placental abnormalities, one had multiple congenital anomalies including an abdominal wall defect, one had a cystic adenomatoid malformation, and one had an open spina bifida with a confirmatory amniocentesis.

Thirty-one patients with open neural tube defects underwent elective abortion; twenty-eight of these cases had been diagnosed by ultrasonography and the other three had diagnostic amniocenteses but normal ultrasonography results. In the case of the twins with one affected fetus, a selective termination of the affected twin was performed in utero with subsequent delivery of one normal infant at 34 weeks' gestation. One fetus with open spina bifida diagnosed by ultrasonography and amniocentesis was lost to follow-up after the parents decided to continue the pregnancy. Each of the two patients with equivocal sonograms for open spina bifida and normal amniocentesis results was delivered of a normal infant.

Of the 20 cases of abdominal wall defects, 14 were terminated; the one fetus with concomitant oligohydramnios died in utero. Five patients continued their pregnancies including the patient with a twin pregnancy in which both fetuses had gastroschisis. Both twins are alive and well after neonatal surgery to correct the defects. One fetus with an abdominal defect and multiple other anomalies was lost to follow-up; in all other patients the ultrasonographic and amniocentesis diagnoses were confirmed.

In the group of 22 patients with oligohydramnios there were six normal singleton babies and one set of normal twins delivered. There were five spontaneous

Table II. Confirmed abnormalities diagnosed by amniocentesis alone

Abnormality	*No. of patients (n = 442)*
Chromosomal	
With additional abnormalities seen ultrasonographically	4
With normal sonograms	
Significant	3
Minor	2
Open spina bifida	3
Hamartoma	1

Table III. Outcome of pregnancy in patients with elevated maternal serum AFP and normal detailed fetal sonograms*

Outcome	*Normal amniocentesis results*	*Abnormal amniocentesis results*
Normal outcome	316	4
Abnormal baby at birth	5	4
Stillbirth	4	0
Spontaneous abortion	5	0
Elective abortion of normal fetus	0	1
Elective abortion of abnormal fetus	0	5
Neonatal death	3	0

$n = 347$.

*Excludes patients who refused amniocentesis or were lost to follow-up.

abortions, four elective abortions, one neonatal death after a premature delivery, and one baby with a club foot that was not detected prenatally. Four patients were lost to follow-up.

In the 21 patients with placental abnormalities diagnosed by ultrasonography, there was one spontaneous abortion and one premature delivery, both in patients with abruptio placentae. Two patients were lost to follow-up and the remainder had normal outcomes.

The remaining abnormalities diagnosed by ultrasonography were confirmed either at birth or by pathologic examination at termination in those cases with follow-up.

Outcomes in the group with normal fetal sonograms are listed in Table III. There were five elective abortions performed on the basis of amniocentesis results that yielded abnormal fetuses—three cases of open spina bifida, one hamartoma, and one XYY chromosomal anomaly. Infants were delivered in the four other cases of chromosomal abnormalities diagnosed by amniocentesis.

Congenital anomalies not diagnosed by ultrasonography or amniocentesis included one patient with congenital hypothyroidism, two with hypospadias, and two with cleft lip.

In the group with normal ultrasonography and normal amniocentesis results, there were five spontaneous abortions including one that occurred 3 days after amniocentesis. This constitutes a fetal death rate of 0.2% from amniocentesis. There were four stillborn infants and three neonatal deaths.

There was one elective abortion of a normal fetus (described in this article) after amniocentesis revealed an elevated amniotic fluid AFP level (20 MOM) and a weakly positive acetylcholinesterase level.

Comment

The results of this series support a complementary role for ultrasonography and amniocentesis in the evaluation of patients referred with elevated maternal serum AFP levels. Other series have also supported the conclusion.[4]

Although the primary goal of the California Maternal Serum α-Fetoprotein Screening Program is the detection of open neural tube defects, in this series only 5% of patients referred had such abnormalities. Fourteen percent of patients referred had other abnormalities diagnosed by ultrasonography or amniocentesis.

Ultrasonography was 90% sensitive in the diagnosis of open neural tube defects in this series. Published series have shown similar sensitivities.[5] There were three false-negative diagnoses by ultrasonography. Use of amniocentesis as a complementary procedure improved the sensitivity of detection of open neural tube defects to 100%. The three false-negative cases of open spina bifida occurred during the first 6 months of our screening program and, as reported previously, changes in scanning protocols[6] as well as more recently described intracranial ultrasonographic signs associated with spina bifida[7, 8] appear to have increased our accuracy in the ultrasonographic diagnosis of this anomaly.

Ultrasonography may be technically difficult because of such factors as maternal body habitus, fetal lie, fetal motion, and oligohydramnios. In such cases the examination may lead to equivocal results. As in the two equivocal cases reported here, amniocentesis may rule out the diagnosis of open spina bifida.

Conversely, it must be remembered that amniocentesis results may also be equivocal. In four patients in this series amniotic fluid AFP results were elevated but less than 3 MOM and acetylcholinesterase results were negative. All four patients had extensive fetal ultrasonographic results that showed no abnormality and all four patients were delivered of normal babies.

A more difficult situation arises in the case of a normal sonogram when the amniotic fluid AFP level is significantly elevated but the acetylcholinesterase determination does not unequivocally support the diagnosis of a neural tube defect. There were two such cases in this series and both pregnancies were terminated; one fetus had a hamartoma at the base of the spine whereas the other fetus was normal. Perhaps repeat detailed ultrasonographic examination after amniocentesis results are known and at a more advanced fetal age would help to differentiate such cases in the future.

Chromosomal aberrations without other fetal anomalies have been reported in patients seen for evaluation of elevated maternal serum AFP levels.[9] Chromosomal aberration can also be associated with most of the anomalies diagnosed by ultrasonography in this series.[10, 11] We had nine cases of chromosomal abnormalities diagnosed in this series. Four were associated with ultrasonographically visible abnormalities and five were not. Such information is useful not only in evaluation of the current fetus but also can be helpful in genetic counseling if future pregnancies are desired.

In this series one spontaneous abortion occurred 3 days after amniocentesis and may have been attributable to the procedure. This constitutes a fetal death rate of 0.2% from amniocentesis. Although there is a risk of fetal death because of amniocentesis, this appears to be low enough to justify use of the procedure to increase prenatal diagnostic accuracy in 3% of cases.

The remainder of the spontaneous abortions in patients with normal ultrasonographic results occurred more than 1 week after amniocentesis. This group and those with stillbirths and neonatal deaths are considered to be reflective of the increased risk of abnormal outcome in patients with elevated maternal serum AFP levels and normal ultrasonographic and amniocentesis results.[5, 12, 13]

A maternal serum AFP screening program can be highly effective in the prenatal diagnosis of fetal anomalies. Such a screening program requires close cooperation between the sonologist, the obstetrician, and the geneticist for optimal prenatal diagnosis and care. Fetal ultrasonography can frequently determine the cause of an elevated maternal serum AFP level and should be the first examination used in the evaluation of patients with maternal serum AFP elevations. If a clear structural anomaly is visualized on fetal ultrasonography and the parents do not wish genetic counseling based on chromosome analysis for consideration of future pregnancies, then amniocentesis can be obviated. Patients with truly elevated maternal serum AFP levels who have normal fetal sonograms or who have abnormal sonograms and desire counseling should undergo amniocentesis.

Discussion

DR. LOUIS BARTOLUCCI, San Francisco, California. Dr. Hanson reports again on the results of the California Maternal Serum α-Fetoprotein Screening Program at the University of California, Davis Medical Center. The study now spans a period of 2½ years and concerns 681 patients referred to that institution for levels of maternal serum AFP over 2.5 MOM in singletons and 4.5 MOM in twins.

I am happy to see that his protocol now includes basic and detailed ultrasonographic studies before invasive procedures are advised. This is a welcome change from the earlier protocol that prescribed level II ultrasonography only if amniotic fluid AFP levels were found abnormal.[1]

The main concern I have about this important study and its implications for our patients has to do with the unequivocal statement made by Dr. Hanson et al. that patients with truly elevated maternal serum AFP levels who have normal fetal sonograms should undergo amniocentesis.

What is proposed and in effect mandated by the State of California is to advise patients to undergo an invasive procedure to increase the sensitivity of the maternal serum AFP screening test. The same position is generally taken by similar programs around the country at this time.[2, 3]

I wonder whether we should review this position in light of the advances made by ultrasonography in instrumentation and operator skill.

The attending obstetricians are faced with patients who have been alarmed by a screening test that unexpectedly assigned their pregnancy to a high-risk category. If they are to be fair in their counseling they must know well the risks and benefits of the course of action advised.

The predictive value of an abnormal screening test, such as maternal serum AFP, in an unselected population is strongly dependent on the prevalence of the disease the test is devised to uncover.[3] The prevalence of open neural tube defects and some other conditions associated with elevated values of maternal serum AFP levels is low in this country,[4] consequently the predictive value of an abnormal maternal serum AFP level will be low even if the sensitivity and specificity of the test were high. Conversely the predictive value of a normal maternal serum AFP level is expected to be high at such low prevalence of the disease.

Amniocentesis carries a small but definite risk to the fetus[6] and, like all invasive procedures, a small risk to the mother.[7]

Ultrasonography carries only one risk in so far as we know to date—the risk of missing an anomaly.

Dr. Hanson reports no maternal complications from the 442 amniocenteses in his study and one fetal death for a 0.2% fetal complication rate. One could, however, regard the death of the normal fetus because of false-positive amniotic fluid AFP results as an amniocentesis-related death. The same objection could be raised to a lesser degree about the aborted fetus with hamartoma, a benign, generally self-correcting condition.

An attempt should be made to quantify risks and benefits for the patient and then allow her to make the final decision.

Reports from perinatology centers around the country are beginning to appear in which the advisability of amniocentesis is questioned in the presence of a normal detailed sonogram.[8]

An exemplification of this trend can be found in a recent article by Nadel et al.[9] from the Departments of Obstetrics and Gynecology and Radiology of Harvard Medical School that addresses precisely the issue of need for amniocentesis in cases of elevated maternal serum AFP levels after a negative targeted ultrasonographic study. The article concludes that because the risk of abortion as a result of amniocentesis is higher than that of missing anomalies commonly associated with high levels of maternal serum AFP, some patients may elect to forgo amniocentesis.

DR. DURLIN E. HICKOK, Seattle, Washington. Dr. Hanson, I want to ask about the patients referred for evaluation of elevated maternal serum AFP levels who appear to have placental abnormalities. There have been several articles[1, 2] suggesting that up to 60% of such patients have evidence of subchorionic hemorrhage, placental thickening, or placental sonolucencies. Can you provide more detail about the percentage of those cases in your series that were offered amniocentesis, had amniocentesis, and had a chromosome abnormality? I understand that many of the cases of elevated maternal serum AFP levels, the so-called false-positives that are associated with placental abnormalities, may be from fetomaternal hemorrhage. Is there any way that we can be more specific in this diagnosis? Is this a broad category for which we might eliminate amniocentesis altogether?

REFERENCES

2. Fleischer AC, Kurtz AB, Wapner RJ, et al. Elevated alpha-fetoprotein and a normal fetal sonogram: association with placental abnormalities. AJR 1988;150:881-3.

DR. RUSSELL K. LAROS, San Francisco, California. If my arithmetic is right, the perinatal mortality in the patients with high maternal serum AFP levels and normal ultrasonography results was about 24 per 1000. What do you recommend to the practicing obstetrician for antenatal surveillance in this group?

DR. HANSON (Closing). Dr. Bartolucci, I share your concern, especially in view of a recent article by Benacerraf.[1] I do think that we need to reexamine the necessity for amniocentesis in cases of increased maternal serum AFP levels and normal level II ultrasonographic examinations. In California we are tied to the guidelines of the State of California Genetic Disease Branch.

Dr. Laros, I think you already know the answer to your question. We have a letter that we send to referring practitioners that disturbs many of them. We recommend that patients with elevated maternal serum AFP levels, normal amniocentesis, and normal level II scans be followed up as one would any high-risk obstetric patient. The details are not specified for medicolegal purposes. This recommendation is made on the basis of an article written by Crandall's group[2] that shows increased risk of adverse pregnancy outcomes in such patients. There is a correlation with the level of AFP. The higher it is, the greater the risk.

Dr. Hickok, I do not have an answer to your question. We see many placental abnormalities, particularly placental lakes. It is a relief when the amniocentesis reveals discolored fluid. Frequently we can confirm that there has been bleeding and more than likely this is the cause of the elevated maternal serum AFP level. Of course, these patients probably should be considered high risk because they have had bleeding at some time in the past. I still do not have the confidence, though, to say that everything is okay without having the chromosomes. The number of chromosomal abnormalities in these patients is very low. Certainly we have picked up some that have had chromosomal abnormalities and have had discolored fluid and have gone on to lose the pregnancy. However, I do not know of any way with ultrasonography alone that we can say ahead of time and with total confidence that there is a placental abnormality that is the only cause of the abnormal AFP level and that we do not need to do any further tests.

Preeclampsia as the great impostor

Robert C. Goodlin, MD
Denver, Colorado

In contrast with a generation ago when preeclampsia was misdiagnosed as medical or surgical disease unrelated to pregnancy, today's diagnostic errors are those that consider surgical and medical problems as either pregnancy-induced hypertension or as the hemolysis, elevated liver enzymes, and low platelet count syndrome. Eleven case histories are presented of significant medical or surgical problems that were initially diagnosed as hemolysis, elevated liver enzymes, and low platelet count syndrome or pregnancy-induced hypertension. The incorrect diagnosis of medical-surgical cases during pregnancy often meant that appropriate therapy was delayed and that the rate of iatrogenic prematurity was increased. (Am J Obstet Gynecol 1991;164:1577-81.)

Key words: Misdiagnosis, hemolysis, elevated liver enzymes, and low platelet count syndrome, pregnancy-induced hypertension

In 1975 the concept of preeclampsia as a great imitator was presented to the Pacific Coast Obstetrical and Gynecological Society. Preeclampsia (gestosis) was misdiagnosed as viral hepatitis, cholangitis, lupus erythematosus, immunogenic throbocytopenic purpura, detached retina, and gastric ulcer. Fifteen years later, as judged by cases seen in our hospitals and in review of records for possible litigation, the types of diagnostic errors have come full circle. Physicians of all specialties are being deceived into making erroneous diagnoses of pregnancy-induced hypertension or the syndrome of hemolysis, elevated liver enzymes, and low platelet count (HELLP syndrome) when the patient actually has a disease process unrelated to pregnancy. Under these circumstances, delivery does not necessarily improve the patient's illness and worse yet, appropriate therapy is often delayed.

Summaries of some of the cases that were misdiagnosed as toxemia or HELLP syndrome are described in this article (Table I). The patients were seen over 14 years at the University of California Hospital at Davis, University of Nebraska Hospital in Omaha, University of Colorado Health Science Center in Denver, and Denver General Hospital.

Case histories

Cardiomyopathy (two cases). A 34-year-old gravida 6, para 4 woman at 33 weeks' gestation was referred because of recurrent toxemia. On admission her blood pressure was mildly elevated and she had severe orthopenia. A chest roentgenogram showed an enlarged heart and pulmonary edema. The pulmonary wedge pressure was elevated and did not respond to furosemide. Because the patient was considered to have pregnancy-induced hypertension, labor was induced with delivery of a 1850 gm infant who had a stormy neonatal course. Post partum the patient had no evidence of pregnancy-induced hypertension. The patient continued to have congestive failure and eventually a cardiac biopsy was done. This showed cardiomyopathy, probably of viral cause. She never recovered and died 7 months post partum while awaiting a cardiac transplant. The other patient was first seen in a similar fashion and recovered from cardiomyopathy.

Dissecting aortic aneurysm (two cases). A 34-year-old gravida 5, para 4 woman was referred for severe HELLP syndrome because her liver enzymes were very high (serum glutamate oxaloacetate transaminase level >3600 U) and with a fetal death. On arrival at the hospital she was somnolent and complained only of neck and chin pain. While in the examining room she became hypotensive and totally unresponsive. She was taken immediately to the operating room for possible liver rupture. At laparotomy, necrosis of abdominal contents was found. She had a dissecting aortic aneurysm beginning at the level of the ascending arch and continuing to the level of the aortic bifurcation. She died on the operating table as did the other patient.

Cocaine abuse (three cases). A 22-year-old gravida 3, para 2 woman was admitted at 24 weeks' gestation for HELLP syndrome (serum glutamate oxaloacetate transaminase level 82 U; platelet count 105,000; blood pressure, 180/118 mm Hg). The first pregnancy was normal. Urine toxicology screening showed cocaine. After 20 hours of hospitalization, all abnormalities had begun to return to normal. She was discharged 1 week later with a diagnosis of probable chronic hypertension.

Table I. Misdiagnosed medical-surgical cases during pregnancy

Correct diagnosis	*Initial diagnosis*	*No. of cases*	*Maternal mortality (%)*	*Perinatal mortality (%)*	*Therapy delay**
Cardiomyopathy	PIH	2	50	0	Yes
Dissecting aortic aneursym	HELLP	2	100	100	No
Cocaine abuse	HELLP	3	0	0	No
Chronic renal disease	PIH	14	0	53	Yes
Acute fatty liver	HELLP	3	100	100	Yes
Gangrenous gall bladder	HELLP	4	0	0	Yes
Glomerulonephritis	PIH	2	0	0	Yes
Immune thrombocytopenia	HELLP	4	0	0	Yes
Lupus erythematosus	HELLP	3	0	100	Yes
Pheochromocytoma	PIH	2	100	100	No
Ruptured bile duct	HELLP	1	0	0	Yes

PIH, Pregnancy-induced hypertension or preeclampsia; *HELLP,* hemolysis, elevated liver enzymes, low platelet count syndrome.
*Significant delay in appropriate medical-surgical therapy that probably increased morbidity.

At 31 weeks' gestation she was delivered of an infant prematurely, with a positive cocaine screening results liver abnormalities, and hypertension. Two other patients have been seen at 33 to 36 weeks' gestation with positive cocaine screening results and were initially considered to be examples of HELLP syndrome. With hospitalization, the abnormalities cleared without delivery.

Essential hypertension and chronic renal disease (14 cases). We reviewed the charts of 48 women younger than age 45 years who were referred for dialysis or renal transplant. It was possible to obtain obstetric care information on 14 of the patients. Of these 14 patients all were hypertensive during the pregnancies and 12 were diagnosed as having preeclampsia or pregnancy-induced hypertension. Eleven were delivered of infants before 38 weeks' gestation with only eight surviving children in the group of 15 fetuses. Whereas preeclampsia is frequently superimposed on existing vascular disease, only five charts indicated that the obstetrician recognized the seriousness of the underlying renal-vascular disease through appropriate testing. The records indicated that only two patients were counseled about the serious nature of the renal disease and provided with adequate medical follow-up.

Acute fatty liver of pregnancy with hypoglycemia (three cases). A 23-year-old gravida 1 woman with 5 years' infertility was seen on referral for twins and HELLP syndrome at 26 weeks' gestation. Laboratory work showed serum glutamate oxaloacetate transaminase values four times the upper limit of normal, a platelet count of 55,000, a serum creatinine value of 1.6 mg%, and a blood sugar level of 34 mg%. She was normotensive. Despite the marked hypoglycemia, her care was temporized with attempts to elevate the blood sugar level and she was given steroids for fetal lung maturity. Liver function became more abnormal, the hypoglycemia worsened, renal and pulmonary function deteriorated, and she suddenly died on her fifth hospital day. A postmortem cesarean section was performed; neither newborn survived. At autopsy, acute fatty liver was present. Neither of the other two patients with marked hypoglycemia survived.

Gangrenous or ruptured gall bladder (four cases). A 25-year-old multigravida was seen in the first trimester because of upper abdominal pain that was diagnosed as heart burn. The pregnancy was otherwise uneventful until 26 weeks' gestation when she was admitted to a hospital with severe right upper-quadrant pain and hypertension (a 15/40 mm Hg rise in blood pressure over a low value in the second trimester). Liver enzymes were 1.5 times the upper limit of normal and the platelet count was 125,000. A diagnosis of HELLP syndrome was made even after obtaining medical consultation. An immediate cesarean section was done. On the second postoperative day she had an emergency cholecystectomy for a gangrenous gall bladder. The mother's postoperative course was prolonged. Unfortunately, the 780 gm infant had a very stormy neonatal course and by age 2 years blindness and cerebral palsy were diagnosed. The other three patients also had postpartum cholecystectomy for ruptured or gangrenous gall bladder, but their infants had no problems.

Glomerulonephritis (two cases). A 31-year-old gravida 1 woman was referred for presumed preeclampsia at 29 weeks' gestation because she was spilling 6 to 8 gm of protein a day. Except for a low serum albumin value (2.1 mg/dl) the laboratory results were normal. Her blood pressure was moderately elevated. She was treated with daily intravenous infusions of albumin. After 2 weeks of hospitalization the pregnancy was terminated because of severe hypertension and massive proteinuria (14 to 18 gm a day). The clinical course worsened post partum and after a renal biopsy the correct diagnosis of type 1 membranoproliferative glomerulonephritis was made. She had a rapid response to corticosteroids. The other patient also responded to steroids.

Immunogenic thrombocytopenia purpura (four cases). An 18-year-old gravida 1, para 0 woman was admitted in labor at term. The initial laboratory work up showed a platelet count of 52,000. Her blood pressure was mildly elevated (144/88 mm Hg) and a diagnosis of HELLP syndrome was made. She was treated with magnesium sulfate and was subsequently delivered of an infant by cesarean section because of failure to progress. Her 3150 gm infant did well except for a platelet count of 40,000 on the third day after birth. Post partum, her platelet count declined to a low of 15,000 and a diagnosis of immunogenic thrombocytopenic purpura was made. She finally responded to a splenectomy. The other three patients responded to medical therapy.

Lupus erythematosus (three cases). A 27-year-old gravida 5 woman with no living children was referred because of severe HELLP syndrome and eclampsia at 24 weeks' gestation. The lupus, diagnosed 6 years previously, was considered to be under good control with only 15 mg of prednisone a day. Immediate past history indicated a recent grand mal seizure, severe hypertension, renal failure, thrombocytopenia, and elevated liver enzyme values. Although a serum complement value was not available, we agreed with the diagnosis of severe preeclampsia that was not responding to therapy, and the pregnancy was terminated at 24 weeks' gestation. Unfortunately, the severe lupus became obvious with continued seizures not responsive to magnesium sulfate and worsening of other symptoms. With appropriate lupus therapy, she did respond after prolonged hospitalization. The other two cases of unsuspected lupus also had inappropriate neonatal deaths.

Malignant pheochromocytoma (two cases). A 31-year-old gravida 3, para 2 woman was referred for severe pregnancy-induced hypertension at 24 weeks' gestation. In the hospital there was marked variability of blood pressure with episodes of increased vasomotor activity and the blood urea nitrogen value was 31 mg/dl. The urine showed significant increases in metanephrines and vanillylmandelic acid. Magnetic resonance imaging showed multiple nonadrenal masses. Blood pressure control with phenoxybenzamine was not successful and at 26 weeks' gestation she was delivered of a 510 gm female infant who did not survive. At the time of cesarean section, wide spread metatastic masses were found throughout the peritoneal cavity. The patient died 6 months post partum despite chemotherapy and radiation therapy. The other patient also died without a living newborn.

Ruptured bile duct (one case). A 22-year-old gravida 1 woman was transported to our hospital at 35 weeks' gestation because of severe HELLP syndrome. She was admitted with severe right upper-quadrant pain, markedly elevated liver enzymes, a platelet count of 121,000, and a white count of 34,000. Blood pressure was slightly elevated. After 8 hours of attempted induction of labor, an emergency cesarean section was performed because of fetal distress. On opening the peritoneal cavity, gross bile was encountered. A ruptured bile duct was eventually found and the patient required a Roux-en-Y hepaticojejunostomy. She was on the operating table for 9 hours and had a prolonged postoperative course. The infant was severely depressed at birth but did well.

Incomplete follow-up. Among patients with the diagnosis of HELLP syndrome during pregnancy, referring physicians have reported three patients with subsequent lupus erythematosus and four patients with immunogenic thrombocytopenic purpura some 5 to 9 years after the affected pregnancy. The patients had all been considered to have recovered completely at the time of the postpartum examination.

Comment

Lupus anticoagulant antibodies have been implicated in patients with preeclampsia and thrombocytopenia but we have not found a single positive case in screening more than 100 patients with apparent preeclampsia. Thrombotic thrombocytopenic purpura, another medical problem confused with preeclampsia, was correctly diagnosed in two patients who died. No other cases of thrombotic thrombocytopenic purpura were knowingly misdiagnosed as HELLP syndrome.

HELLP syndrome is not a new disease.[1-3] Despite the wide interest and intervention therapy in patients with HELLP syndrome, there is no evidence that the outcome of these patients has improved since Weinstein developed the acronym. Whereas the incidence of eclampsia has continued to decrease, the diagnosis of severe preeclampsia has increase.[4] In contrast with the present concept that those with the abnormal liver test results and with no or mild thrombocytopenia or hypertension are emergent cases, in the past these were usually considered cases of viral hepatitis. They were treated with bed rest and they usually had a good outcome. Even when the disease process was severe, the cases were appropriately handled.[5] Today, even with relatively mild cases, the incidence of iatrogenic prematurity has increased as a consequence of considering all grades of the HELLP syndrome as severe preeclampsia.

It is much too easy to ascribe almost any disease in pregnancy to be a result of pregnancy-induced hypertension or HELLP syndrome.[3] Previously the misdiagnosed cases of preeclampsia led to inappropriate procedures, such as cholecystectomy for right upper-quadrant pain. Although an error, this inappropriate therapy itself was seldom life-threatening. But as recounted in these case histories, to incorrectly diagnose life-threatening surgical-medical illness as HELLP syndrome can endanger the patient's life or seriously prolong the illness. The correct diagnosis would not have prevented the maternal deaths described here, but as shown in Table I, it would probably have reduced maternal morbidity and iatrogenic prematurity. It was previously suggested that obstetricians should become complete physicians and manage these patients without consultation.[1] As shown by these cases of lupus and immunogenic thrombocytopenic purpura, after a thorough evaluation is done by the obstetrician in atypical cases of HELLP syndrome it can be beneficial to the patient for the obstetrician to obtain knowledgeable consultation.

It is especially important to recognize the significance of persistent hypoglycemia in patients with possible HELLP syndrome. It indicates severe liver failure[3, 6] and immediate delivery appears to be the patient's only hope inasmuch as survivors with prolonged hypoglycemia are rare.

To assume that right upper-quadrant abdominal pain in late pregnancy is a result of HELLP syndrome without an ultrasonographic examination of the gall bladder and liver to rule out gall bladder disease or a liver hematoma can be remiss, although others consider the test to have a low yield. Gall stones can be totally unrelated to the management of HELLP syndrome but not liver hematomas.[7]

Whereas it may not always be possible to rule out immunogenic thrombocytopenic purpura and systemic lupus in these cases of suspected HELLP syndrome, an effort should be made because delivery may aggravate the clinical course. In patients with persistent or recurrent hypertension, careful follow-up should be arranged to rule out underlying renal or cardiovascular disease. Such can significantly modify the patient's life expectancy.

Steroids and low-dose aspirin have been suggested for cases of apparent HELLP syndrome that are not planned for immediate delivery.[8, 9] Even when the diagnosis of HELLP syndrome is correct, these drugs may possibly improve abnormal liver test results and platelet values of patients with preeclampsia, and when the correct diagnosis is lupus or immunogenic thrombocytopenic purpura, they can be of significant benefit.

Discussion

DR. RALPH BENSON, Portland, Oregon. Dr. Goodlin has come full circle since his 1975 finding that the symptomatology of preeclampsia-eclampsia is often misdiagnosed as a nonobstetric problem. Today he has shown that obsetricians may fail to diagnose medical or surgical problems that masquerade as pregnancy-induced disorders. Although in the later series most parturients survived, many neonates died, usually as a result of treatment based on incorrect diagnoses or early intervention.

Unusual diseases are always intriguing. How they affect pregnancy and how pregnancy affects them may not be entirely clear to the observer. Of the 40 cases reported, 20 were initially thought to be examples of the HELLP syndrome—still presumed by some to be a potentially critical variant of severe preeclampsia-eclampsia. In Dr. Goodlin's current series, the presumptive diagnosis of the HELLP syndrome i.e., hemolysis, elevated liver enzymes, and low platelet count could not be substantiated in any instance. Accepted medical or surgical diagnoses were finally made in each case, however,

Weinstein described the HELLP syndrome in 1954. Early on, obstetricians gave this diagnosis more than tentative recognition. Nevertheless, the symptom complex was ill-defined, variable, and uncommon. Hence a thorough study of an adequate number of patients was delayed. Soon, skeptics including Dr. Goodlin began to question HELLP syndrome as an entity.

In 1985, Beller and associates in Germany concluded from hematologic studies, renal biopsy specimens, and patient outcome that a medical disorder complicating pregnancy (e.g., liver disease, systemic lupus, was the basic problem in the HELLP syndrome).

Kirschbaum's[1] editorial comment in the 1987 *Year Book of Obstetrics and Gynecology* relating to Beller's work is most insightful: "The acronym separates out a portion of the pathology of severe preeclampsia in a way not pathologically coherant and that may be useful in the management of the disorder" (severe preeclampsia-eclampsia). Dr. Goodlin's article drives another nail in the HELLP coffin.

When children learn that Lewis Carroll's dragon, the Jabberwock, is dead they are relieved. When they learn the dragon was bogus, they are delighted. Similarly, although I am older, I am most pleased to know that the dragon HELLP syndrome was never a true obstetric entity.

Dr. Goodlin has stressed the need for a team approach to problem obstetric cases. Clearly even experienced obstetricians should confer more often when the diagnoses are questionable or obscure. Moreover, the need for long-term follow-up of hypertensive patients or those with probable metabolic disease must not be forgotten. This will further reduce material and perinatal mortality and morbidity.

Aside from the opportunity to share some of the essence of this unique study, my real reason for speaking is to applaud Dr. Goodlin for his individuality, his curiosity, his ability to ask the proper questions, and his tireless search for correct answers. He deserves special commendation also for presenting 11 papers and seven formal discussions at 13 meetings since his election to the Society in 1971, and he is a nonresident member.

Dr. Goodlin (Closing). I thank Dr. Benson for his kind remarks. I have been privileged to speak often at our meetings, but I also lead the list in number of papers rejected by our Society for publication in the American Journal of Obstetrics and Gynecology. Whereas some of my papers accepted here had been rejected elsewhere, those rejected by the Society have often been subsequently published by other journals. My advice to younger members is to write about accepted concepts, do complicated statistics, and to remember that the difference between a rejected and a published manuscript is often the amount of postage one is willing to spend on submitting it to the various journals. Peer review does not tolerate revolution and therefore I am most grateful to the Society for accepting some of my controversial papers.

I doubt whether obstetricians will pay attention to what we say in Sun Valley about the HELLP syndrome. I fear its concepts are written in stone. About all we can hope for is that in atypical cases, caution will be used before interrupting the pregnancy.

Mechanisms of asphyxial brain damage, and possible pharmacologic interventions, in the fetus

Mauricio I. Espinoza, MD, and Julian T. Parer, MD, PhD
San Francisco, California

An examination of the cellular and molecular mechanisms of neuronal cell damage may lead to the design of pharmacologic interventions during presumed or actual fetal asphyxia. Hypoxia-ischemia in its severest form results in insufficient adenosine 5'-triphosphate production. The most important effect of this is failure of adenosine 5'-triphosphate–dependent membrane functions, which maintain ionic homeostasis, that is, ionic pumping. There is K^+ efflux and Na^+ influx across the cell membrane, depolarization of the cell membrane, opening of the voltage-dependent calcium channels, and entrance of Ca^{++} into the cell. Cytosolic Ca^{++} is also increased by Ca^{++} efflux from the mitochondria and the sarcoplasmic reticulum. Ca^{++} is a toxin in high cytosolic concentrations; it activates phospholipases A and C, which cause membrane breakdown and release of free fatty acids, including arachidonic acid. The membrane is damaged, lysis occurs, and the neuron dies. High cytosolic Ca^{++} also causes release of excitatory amino acids (especially glutamate), which overwhelm the suppressant neurotransmitters, causing seizures, increased metabolism, and aggravation of the insufficient adenosine 5'-triphosphate availability. Thromboxane A_2 is generated from arachidonic acid, increasing smooth muscle tone and thereby worsening the ischemia. Cyclooxygenase activity also results in formation of oxygen-free radicals that contribute to cell membrane damage, lysis, and death. Possibilities for pharmacologic interventions include (1) calcium channel blockers and antagonists, (2) excitatory neurotransmitter blockers, (3) oxygen-free radical scavengers (e.g., superoxide dismutase), (4) cyclooxygenase or prostaglandin synthesis inhibitors, and (5) seizure suppressants (e.g., phenobarbital). Some of these treatments have been shown experimentally to limit neuronal death in the adult and fetus, and after more investigative work they may be applicable to clinical practice. (AM J OBSTET GYNECOL 1991;164:1582-91.)

Key words: Fetal asphyxia, fetal hypoxia, fetal brain damage, fetal pharmacology

Mechanisms of brain damage

Severe fetal asphyxia may have a broad range of effects on the brain, from no evident alteration in brain function to profound cerebral palsy. In past years a large amount of information has been collected on the fetal cardiovascular and respiratory responses to oxygen limitation, giving rise to a better understanding and management of neonatal deterioration induced by asphyxia. Besides these physiologic studies, cellular and biochemical mechanisms involved in the production of brain cell death are being increasingly explored, particularly in the adult with respect to focal (e.g., stroke) and global (e.g., cardiac arrest) hypoxia-ischemia.[1] These studies have shown that complex and interrelated biochemical alterations are triggered during hypoxia-ischemia in mature subjects that ultimately result in neuronal death. Many of these alterations are also being recognized in the immature brain.[2] A thorough knowledge of these biochemical events may lead to recognition of certain steps that may be amenable to pharmacologic intervention to limit or even prevent neuronal cell damage during presumed or actual fetal asphyxia.

Current evidence suggests that, in addition to a severe hypoxic insult, some associated cardiocirculatory failure or collapse is required to produce brain damage.[3] This cardiovascular collapse probably produces a reversal of the initial cerebral vasodilatation observed in the hypoxic fetal brain, therefore adding an actual or relative ischemic component to the hypoxic insult during severe asphyxia in the fetus.

Adenosine 5'-triphosphate insufficiency. Hypoxia-ischemia in its severest form results in insufficient adenosine 5'-triphosphate production.[1, 4] Normally, up to 60% of the adenosine 5'-triphosphate consumed by the cell is used to maintain ionic homeostasis, primarily pumping sodium out of the cell and potassium into the cell. A reduction in adenosine 5'-triphosphate synthesis

6/6/29071

as a result of oxygen limitation therefore severely disrupts ionic equilibrium across membranes.[1-5] Potassium accumulates quickly in the extracellular space, while sodium enters the cell, carrying water with it, with the subsequent development of cellular swelling.

Other consequences derive from this ionic imbalance. First, it has been suggested that increased extracellular potassium may increase oxygen and glucose use by the brain, aggravating the adenosine 5′-triphosphate deficit. Second, extracellular potassium may stimulate glutamate-releasing neurons (see later). Third, and probably most important, as sodium enters the cell and potassium leaves it, the cell membrane depolarizes, leading to the opening of voltage-dependent calcium channels, resulting in calcium influx into the cell[5,6] (Fig. 1).

Role of calcium. Accumulation of calcium in the cytosol has been extensively demonstrated in brain cells undergoing hypoxia-ischemia.[7] This accumulation is produced through several mechanisms in addition to entry by activation of voltage-dependent channels in the plasma membrane. Calcium is also released from mitochondria that are stimulated by the increase in intracellular sodium and free fatty acids and from the endoplasmic reticulum because of the depletion of adenosine 5′-triphosphate.[8] Finally, calcium enters through agonist-dependent channels (see Excitatory amino acids).

Calcium is a toxin in high intracellular concentrations. Therefore the normal cell possesses mechanisms to maintain the free calcium concentration within tight limits.[9] These mechanisms include a calcium-sodium exchange system at the plasma membrane, an adenosine 5′-triphosphate–dependent calcium pump in the plasma membrane, a calcium-hydrogen exchange in the mitochondria, and an adenosine 5′-triphosphate–dependent uptake of calcium by the endoplasmic reticulum. The failure of these protective mechanisms during hypoxia-ischemia as a result of insufficient adenosine 5′-triphosphate contributes to calcium accumulation in the cytosol.

Consequences of accumulation of calcium in the cytosol are multiple (Fig. 2). One of the most damaging seems to be the activation of phospholipases A and C.[5] These reactions lead to membrane phospholipid hydrolysis, with the consequent disruption of cellular and organelle membranes, increase in their permeability, and further unfavorable alteration in ionic distribution. Free fatty acids, including arachidonic acid, are released from the disrupted membranes.[8] Phospholipase C also catalyzes reactions, leading to production of inositol triphosphate, a second messenger that releases calcium from the endoplasmic reticulum, and of diacylglycerol, which contributes to decreased calcium-sodium exchange.[6,8] Both reactions further augment calcium concentration in the cell and amplify its deleterious effects, thus creating a vicious cycle that ultimately destroys the cell.

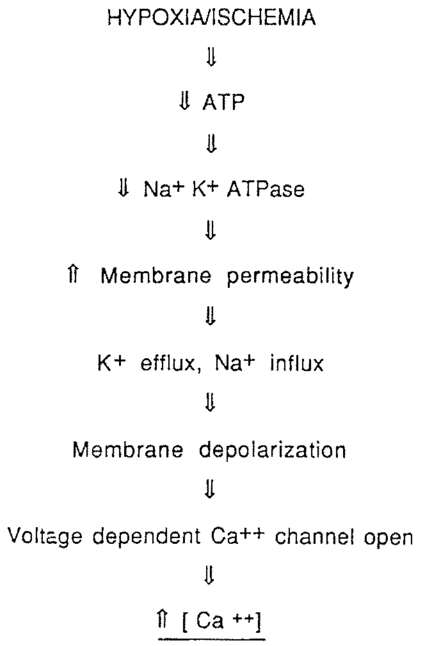

Fig. 1. Consequences of adenosine 5′-triphosphate deficiency after hypoxia-ischemia.

Excitatory amino acids. Among neurotransmitters in the brain, the amino acids glutamate and aspartate play a major role as excitatory neurotransmitters and also as neurotoxins under certain conditions.[10] Three glutamate receptor subtypes have been described,[10] designated as *N*-methyl-D-aspartate, quisqualate, and kainate receptors. These receptors are coupled to ion channels that allow sodium and calcium into the cell[9] (Fig. 3).

There are several lines of evidence that support a role of excitatory amino acids in neuronal damage during hypoxia-ischemia. First, in adults and in fetal lambs glutamate and aspartate increase in the extracellular space of the brain during hypoxia-ischemia. Second, in vivo and in vitro administration of glutamate produces neuronal death in areas of the brain with a higher density of glutamate receptors.[11] Third, glutamate receptor blockers, discussed in detail later, may limit the hypoxic cellular damage in vivo and in vitro.[12]

Neuronal cells that release glutamate are activated during hypoxia by the entrance of calcium into the cells and by the depolarization of these cells (discussed above).[10] A concomitant decrease in the adenosine 5′-triphosphate–dependent uptake of glutamate by the presynaptic membranes contributes to maintain increased extracellular concentrations of glutamate, allowing a prolonged stimulation of its receptors.

Fig. 2. Consequences of increased intracellular calcium.

Two mechanisms of glutamate-induced neuronal damage have been proposed.[10] The first acts within minutes after induction of the insult and involves a massive influx of sodium, and thereby of chloride and water, into the cell, resulting in osmotic load and eventual lysis of cell membranes. A more delayed mechanism of cell damage, occurring up to 24 hours after the insult, involves the influx of calcium through *N*-methyl-D-aspartate–stimulated calcium channels. The resultant increase in cytosolic calcium concentration perpetuates the process by further activating glutamate release and the other damaging mechanisms already discussed. In addition, glutamate-mediated damage of neuronal cells also results from its ability to enhance or induce seizure activity,[10] which contributes to the adenosine 5′-triphosphate depletion.

Arachidonic acid cascade. Arachidonic acid is one of the free fatty acids released from membranes by the calcium-activated phospholipases A and C.[6] Arachidonic acid initiates a cascade of biochemical reactions that lead to the production of prostaglandins, thromboxanes, and leukotrienes. In this regard both prostacyclin and thromboxane increase in the cerebrospinal fluid after cerebral ischemia in cats.[13]

Under normal conditions a balance exists between prostacyclin, which vasodilates vessels and inhibits platelet aggregation, and thromboxane A_2, which vasoconstricts vessels and promotes platelet aggregation (Fig. 4). The result of this equilibrium is an optimum blood flow in the microcirculation. However, some reactions in the prostaglandin cascade lead to production of oxygen free radicals as byproducts,[2] one of the actions of which is to inhibit prostacyclin synthetase,[14] decreasing the concentration of prostacyclin and thus leaving thromboxane A_2 unbalanced. Such imbalance promotes vasoconstriction and platelet aggregation, thereby worsening the ischemia and oxygen supply to brain cells. In addition, arachidonic acid contributes to the prolonged stimulation of glutamate receptors by blocking glutamate uptake.

Oxygen free radicals. Free radicals are molecular species with an unpaired electron in the outer orbit that renders them very reactive, with a strong tendency to initiate chain reactions that result in lipid membrane and deoxyribonucleic acid peroxidation and cell damage. Normally, >80% of the oxygen consumed by the cell is reduced by cytochrome oxidase[15] without production of oxygen free radicals. The remaining 10% to 20% follows other oxidation-reduction reactions in the cytoplasm and mitochondria that produce the superoxide anion radical.[15] To protect themselves against the deleterious effects of these oxygen free radicals, the cells possess an array of enzymatic and nonenzymatic defenses that include catalases, endoperoxidases, and dismutases among the enzymes and glutathione, cholesterol, ascorbic acid, and tocopherol among the scavengers.[1]

Oxygen free radicals are generated in the tissues during and well after the end of the hypoxic-ischemic insult (Fig. 5). During hypoxia, oxygen free radicals are formed as byproducts in the synthesis of prostaglandins by the action of the enzymes cyclooxygenase and lipoxygenase.[2, 14]

Another source is the reaction that synthesizes uric acid from adenine nucleotides.[2] As adenosine 5′-triphosphate degrades during hypoxia, adenosine

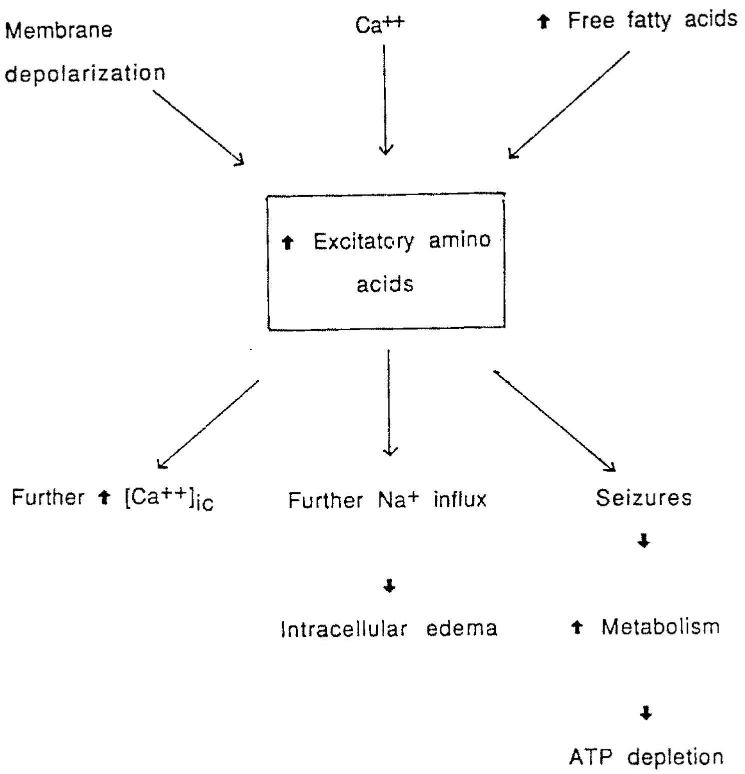

Fig. 3. Sources and consequences of increased release of excitatory amino acids.

5′-monophosphate accumulates and is not rephosphorylated to adenosine 5′-triphosphate because of the lack of oxygen. Therefore more adenosine 5′-monophosphate is converted to adenosine and then to hypoxanthine. Normally, hypoxanthine is converted sequentially to xanthine and uric acid by xanthine dehydrogenase, which uses the oxidized form of nicotinamide-adenine dinucleotide as the acceptor of electrons, without generating free radicals. However, during hypoxia, the enzyme xanthine dehydrogenase is transformed to xanthine oxidase by a reaction that is activated by the increase in the cytosolic calcium concentration. Xanthine oxidase also metabolizes hypoxanthine to uric acid, but instead of the oxidized form of nicotinamide-adenine dinucleotide, it uses oxygen as the acceptor of electrons, generating superoxide anions.

This reaction is particularly important on reintroduction of oxygen into hypoxic-ischemic tissues, which results in the massive production of oxygen free radicals that produce the so-called reperfusion injury over and above the damage already produced during the hypoxia itself. The so-formed oxygen free radicals destroy cells by peroxidation of the membrane lipids in a chain that further disrupts membranes and alters ionic equilibrium.

Summary of mechanisms. In addition to the previously discussed mechanisms, there has been considerable discussion in the literature about the role of lactacidosis, which invariably accompanies hypoxia-ischemia, as a damaging agent by itself. This controversy has been previously reviewed[1,2] and is not further addressed in this article.

The combined action of osmotic changes across the cell membrane, the catastrophic consequences of the uncontrolled accumulation by various mechanisms of calcium in the cells, the increased release of excitatory neurotransmitters, and the enzymatic and oxygen radical–mediated membrane damage overwhelm the defensive mechanisms of the cell, leading to its destruction during and after hypoxia-ischemia. Microvascular alterations produced by imbalances among opposite actions of eicosanoids further aggravate the results of hypoxia-ischemia, joining in the self-perpetuating nature of many of the reactions described above in the process of cellular death.

Strategies for intervention

From the fetal point of view, the best possible treatment for hypoxia-ischemia in utero would be removal from the unfavorable environment, which usually involves emergency delivery of the fetus. However, in

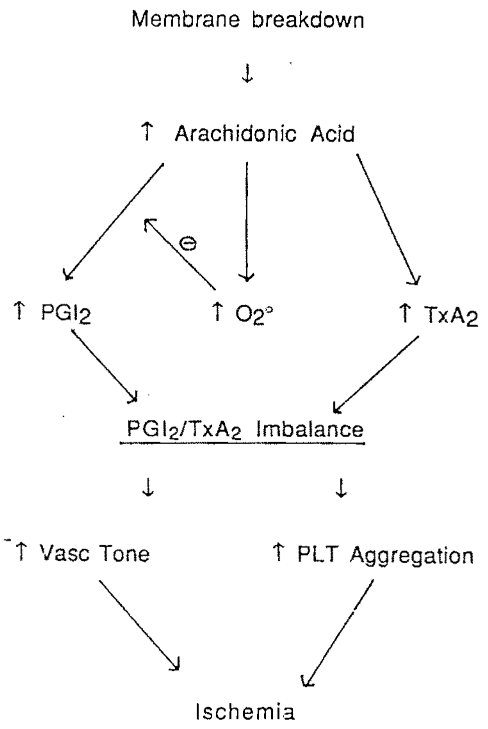

Fig. 4. Causes and consequences of prostacyclin/thromboxane imbalance.

many cases this is not always possible to achieve rapidly. Therefore pharmacologic interventions may prove to be valuable to limit or prevent damage to the brain cells until delivery and extrauterine resuscitation can occur. Such treatment should be aimed to limit the influx of calcium into the cytosol, block the glutamate receptors, inhibit the arachidonic acid cascade, scavenge oxygen free radicals, or save energy expenditure by suppressing seizures (Fig. 6).

Calcium channel blockers. It follows from the above discussion that a major intervention could be to avoid accumulation of calcium in the cytosol. Calcium accumulation cannot be completely abolished because, in the presence of continuing hypoxia-ischemia, the effects of adenosine 5′-triphosphate depletion on calcium distribution cannot be avoided. However, calcium accumulation can be limited by blocking the movements of calcium through voltage- and agonist-activated channels. If successful, these treatments could prevent the activation of enzymes and the release of excitatory amino acids induced by calcium.

Several calcium channel blockers have been experimentally tested. Nimodipine reduced infarct size and improved blood flow in experimental focal ischemia in adult rabbits.[16] Also in adults flunarizine, at a dose of 0.1 mg/kg given intravenously, decreased cell death in some regions of the brain after global asphyxia in dogs. In newborn rats subjected to hypoxia-ischemia, pretreatment with 30 mg/kg intravenous flunarizine improved behavioral scoring and provided histologic protection.[17] In newborn lambs, 3 mg/kg intravenous lidoflazine given during resuscitation after severe asphyxia was associated with improved cerebral blood flow and partial or total recovery of somatosensory evoked potentials.[18] In fetal lambs preliminary reports of the use of 45 mg flunarizine over a 2-hour infusion before total cerebral ischemia have shown a reduction in neuronal death and improvement in electrocortical activity. Flunarizine appears to be a promising agent, because it crosses the brain-blood barrier and has preferential action over cerebral circulation without other major circulatory effects.[17]

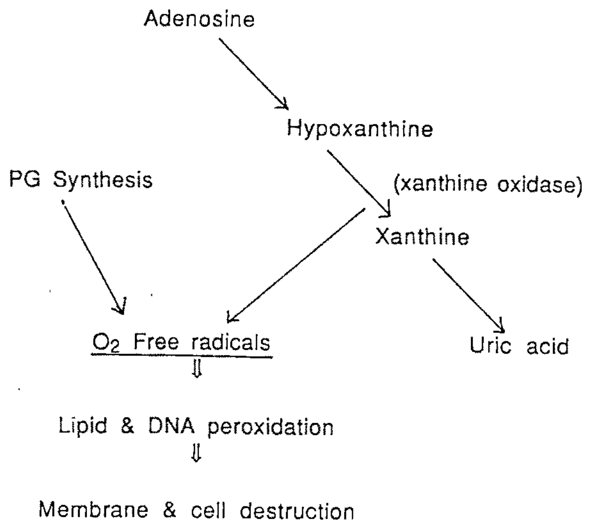

Fig. 5. Sources and consequences of increased oxygen free radicals.

A question has been raised regarding the timing of use of calcium channel blockers to obtain cerebral protection in hypoxia-ischemia. As mentioned, lidoflazine showed protective effects in neonatal sheep when given after severe asphyxia.[18] In contrast, protection with flunarizine was observed in newborn rats only when the agent was given before cerebral hypoxia-ischemia.[17] Certainly more studies are necessary to clarify this issue and others before flunarizine or other calcium channel blockers are used in the treatment of human fetuses suffering from asphyxia.

Excitatory amino acid antagonists. The deleterious actions of excessive release of glutamate during hypoxia-ischemia may be limited by blocking its binding to postsynaptic receptors with a number of antagonists that have been developed.[19] The inhibition of the *N*-methyl-D-aspartate receptor during hypoxia has been studied in vitro and in vivo with competitive antagonists such as 2-amino-7-phosphonoheptanoic acid and noncompetitive antagonists such as phencyclidine, (+)-

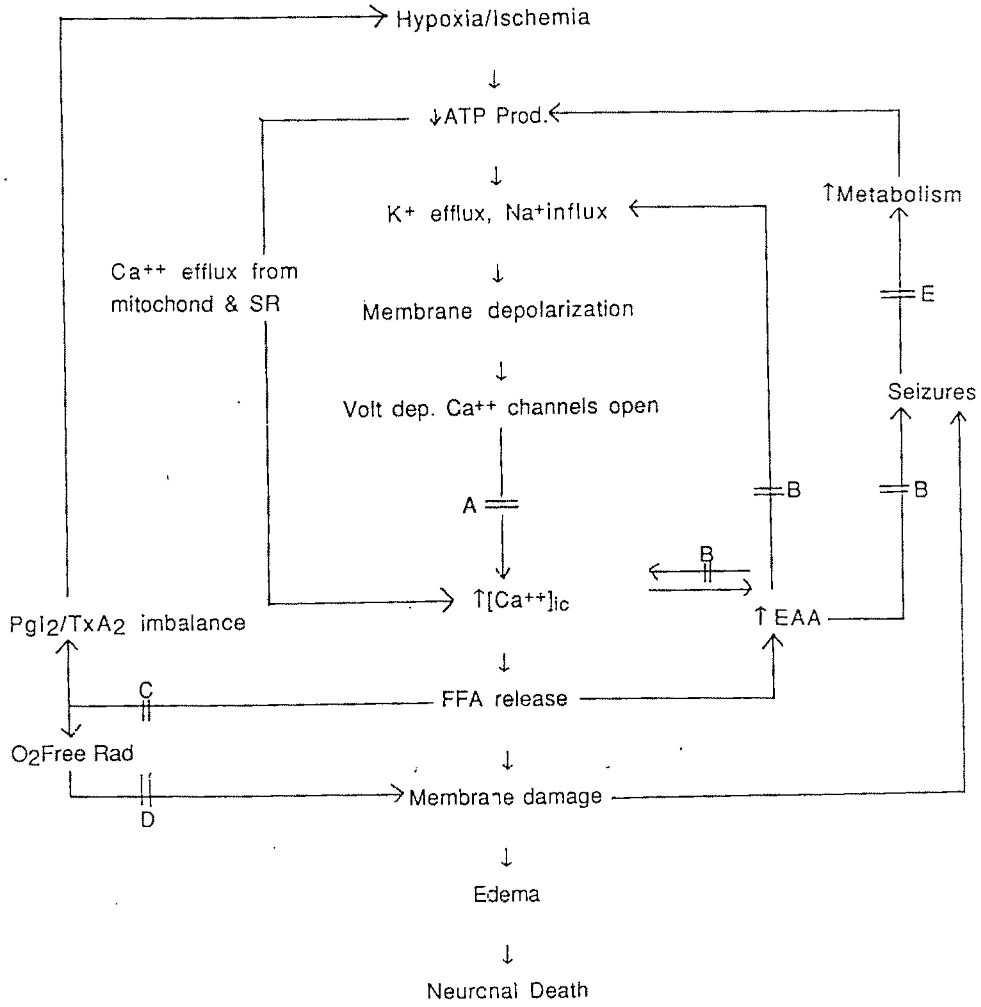

Fig. 6. Metabolic and biochemical events causing neuronal death due to oxygen limitation, and steps that are possibly amenable to pharmacologic intervention. *A*, Ca^{++} channel blockade; *B*, excitatory amino acid antagonists; *C*, arachidonic acid cascade inhibitors; *D*, oxygen free radical scavengers; *E*, seizure suppressants.

5-methyl-10,11-dihydro-^{5}H-dibenzo[a,d]cyclohepten-5,10-imine maleate (MK-801), magnesium, and dextromethorphan.

In adult cats subjected to complete reversible cerebral ischemia, MK-801 in doses >0.5 mg/kg given intravenously before the insult produced a return to the baseline electroencephalogram patterns on restitution of the flow, avoided secondary hypoperfusion, preserved the blood-brain barrier, and maintained the balance between prostacyclin and thromboxane in the cerebrospinal fluid.[13] In rats, local infusion of 2-amino-7-phosphonoheptanoic acid protected against the development of histologic damage induced by ischemia.[12] In newborns, MK 801 (1 mg/kg) given before, or before and after, hypoxia decreased neuronal loss in various regions of the brain in rats, and dextromethorphan (20 mg/kg given intravenously) decreased neuronal damage after ischemia in rabbits. In fetal sheep treatment with MK-801 before or up to 6 hours after cerebral ischemia seemed to abolish the appearance of postischemic seizures. The *N*-methyl-D-aspartate antagonists 2-amino-7-phosphonoheptanoic acid and MK-801 also are potent anticonvulsants. By suppression of hypoxia-induced seizures, energy can be saved and energy-dependent processes can be maintained in the brain.

Interventions to block glutamate receptors may be of particular importance in the fetus and newborn, because the brain seems to be more susceptible to glutamate-mediated damage in perinatal than in adult animals. MK-801 seems to be the most promising agent, because it is potent and crosses the blood-brain barrier. However, the potential toxicity has not been completely studied.

Arachidonic acid cascade inhibitors. Blockade of the prostaglandin synthesis cascade may limit brain cell damage by avoiding the generation of oxygen free radicals that are produced and the consequences of the imbalance between prostacyclin and thromboxane.

Prostaglandin synthesis may be blocked by inhibiting the enzyme cyclooxygenase. Among the cyclooxygenase inhibitors, the preferred drug has been indomethacin. In adult animals indomethacin given before ischemia improved postischemic reperfusion of the brain in dogs, rats, and cats.[20] During the perinatal period indomethacin has been extensively studied with regard to its actions on the closure of the ductus arteriosus and on the regulation of respiration. However, there are no studies addressing the issue of protection of the brain with indomethacin during or after hypoxia-ischemia. Until these studies are done, its value will remain speculative.

The imbalance could be corrected by giving prostacyclin. However, the results of limited studies on the use of prostacyclin during brain ischemia show little, if any, beneficial effects.[21]

Oxygen free radical scavengers. The cellular damage that results from the exaggerated formation of oxygen free radicals during hypoxia-ischemia, and especially during the reperfusion of tissues after ischemia, could be prevented by scavenging oxygen free radicals. The scavenger superoxide dismutase has been shown to improve somatosensory evoked potentials in dogs when given after spinal cord ischemia. Also, in dogs, superoxide dismutase in combination with deferoxamine, which was added to prevent membrane lipid peroxidation, improved cerebral blood flow and facilitated the recovery of somatosensory evoked potentials when it was given during resuscitation after cardiac arrest. The conjugation of superoxide dismutase with polyethylene glycol prolongs circulatory half-life and enhances superoxide dismutase entrance to the cells. This conjugate, when given before local ischemia, decreased the infarct volume in rats.[22] Catalase, an enzymatic scavenger for hydrogen peroxide, also decreased infarct volume in rats.[22] A different strategy is to block hypoxanthine oxidase, the enzyme that generates oxygen free radicals during metabolism of adenine nucleotides, with allopurinol. In rats, pretreatment with allopurinol prevented the loss of reflexes and the formation of cerebral edema after global ischemia.

Pretreatment with the combination of superoxide dismutase and catalase conjugated with polyethylene glycol improved cerebral blood flow after asphyxia in newborn lambs.[23] Also, in lambs, a mixture of three scavengers, mannitol, L-methionine, and magnesium, protected brain functions after cardiac arrest induced by asphyxia.[18] However, in this study a calcium channel blocker also was administered, making it difficult to come to a conclusion about the role of the scavengers. Finally, in immature rats pretreatment with 130 mg/kd allopurinol decreased brain edema and reduced the histologic damage induced by hypoxia-ischemia.

Despite the extensive investigations into prevention of brain and cardiac damage induced by oxygen free radicals, no clinical trials with scavengers have been done in adults,[24] and more research is still needed in the perinatal period before their use is recommended.

Seizure suppressants. Many years ago barbiturates were proposed as agents to prevent asphyxial brain damage because of their ability to reduce brain metabolism and brain oxygen consumption. Since then, most studies have shown that their protective value, if any, is rather small.[25] However, barbiturates continue to be used as a suppressant in hypoxic-ischemic seizures. By controlling seizures, energy can be saved, because it has been shown that seizures increase brain metabolic demands.[26] Therefore in theory barbiturates have a place in the prevention of brain damage during asphyxia in the fetus.

Comment

From the previous discussion, it is clear that many steps in the biochemical process that lead to cell damage are amenable to pharmacologic treatment.

In spite of the fact that most of the present information has been obtained from research in adults, the same mechanisms probably exist in the newborn and fetus. However, the relative importance of each of the mechanisms, and therefore of the steps to be blocked, has not been determined. Because of the multiple interrelations among the different mechanisms, it is possible to speculate that, after necessary extensive animal research, the strategies for treatment will most probably consist of combinations of different agents acting at different steps.

Treatment of the asphyxiated fetus has particular problems that need to be solved. The agent must cross the placenta and the blood-brain barrier without losing activity and without producing side effects in the mother and fetus. Also, the detection of impending or actual fetal asphyxia needs to be improved so that we can better decide when to administer the drugs. In this regard most of the evidence available shows that the best results are obtained when the interventions precede the asphyctic insult. This implies treating fetuses at risk and therefore that the detection of risk needs to be improved. When these and other questions are answered, pharmacologic prevention of brain damage during asphyxia in utero may be possible.

Discussion

Dr. Robert C. Goodlin, Denver, Colorado. This is a significant topic. Cerebral palsy is a major disability of newborn infants. Despite our present high cesarean section rate and the use of electronic fetal monitoring, the incidence of cerebral palsy continues to increase.[1] Twenty-five years ago one of the main obstetric goals was to prevent cerebral palsy. Paul and Quilligan[2] previously estimated that 50% of cases of cerebral palsy were due to intrapartum asphyxia. Last year Naeye et al.,[3] analyzing the same collaborative project data of the 1950s and 1960s, determined that only 6% of cases of cerebral palsy are due to intrapartum asphyxia. I continue to submit an article that asks, "Have the obstetricians given up on cerebral palsy?" The reviewers not only reject it but do so very angrily. They ask what I am trying to do—reverse the concept that obstetricians are no longer responsible for cerebral palsy and attempt to treat something we can do nothing about?

My first question may be a difficult one for you, Dr. Parer. What percentage of cerebral palsy cases are due to intrapartum asphyxia? If you say it is low, then there is no clinical need for this seminar. Since there are only two to four cases of cerebral palsy per thousand deliveries, and only 6% of those are due to intrapartum factors, that means you could successfully treat only 1 in 8000 births if therapy were 100% effective. If you say it is above 10%, I can assure you, you will incur the wrath of obstetricians throughout the world.

Drug therapy for the prevention of asphyxia or asphyxial brain damage is >100 years old. My own studies were done in the 1960s, and I still believe that sedation (barbiturates), atropine, and general anesthesia offer protection for the fetus against asphyxia, although they cause lower Apgar scores. I gather that Dr. Parer disagrees with the idea that these drugs are useful.

During the past decade, fetal or newborn strokes have been diagnosed with increased frequency (about 1 in 1,000 in our hospital) with the newer imaging techniques. Would not therapy for these stroke cases of cerebral palsy be different from those cases caused by generalized asphyxia?

Neonatologists have not been able to offer effective therapy for hypoxic ischemic encephalopathy, even when the event occurs in the newborn. Measurement of hypoxanthine has not been useful, and vitamin E as an oxygen scavenger has been detrimental. Until there is an effective neonatal therapy, I doubt that there will be one that is useful for the fetus.

While reviews are useful, laboratory data are required before clinical applications of this type of intervention therapy are considered.

DR. JAMES C. CAILLOUETTE, Pasadena, California. Dr. Parer and Dr. Goodlin each have addressed a subject that has been a perplexing one at our hospital, as illustrated by this report of a case that occurred in December 1988. A 42-year-old woman, gravida 2, para 2, at 38 weeks' gestation was attending the races at Santa Anita. For several hours she experienced severe back pain, but from the racetrack she went Christmas shopping. When she had even more severe back pain and the onset of vaginal bleeding, she went home and contacted the on-call physician. She was sent directly to the hospital and arrived within 30 minutes, at 8 cm dilatation. Electronic fetal monitoring showed late decelerations and bradycardia. She was taken directly to the delivery room, and the cervix was found to be completely dilated. Artificial rupture of membranes produced port wine fluid with meconium, typical of placental separation. A female infant, approximately term size, with Apgar scores of 2 and 2, was promptly delivered. A resuscitation team of neonatologists were present at the time of delivery and the baby was taken to the newborn intensive care unit. Twelve hours after delivery, the baby had its first and only seizure. She was given phenobarbital at that point. Computed tomographic scans, performed over the next 72 hours, showed progressive atrophy of the right parietal lobe. There has been great discussion and uncertainty on the part of the radiologist, the pediatric neurologist, the pediatrician, and the obstetrician about the pathophysiologic condition. A stroke seems possible. I hope that over time we can have a better understanding of this issue.

DR. CHARLES D. KIMBALL, Seattle, Washington. Dr. Parer, I was much impressed with your review of the molecular events linking fetal asphyxia and the transport of electrolytes across brain cell membranes. However, it seems to me you may have overlooked the profound importance on ion transport of opioid receptor ligands such as β-endorphin. Gautray et al.[1] of the Salk Institute reported several years ago in the GRAY JOURNAL that β-endorphin is elevated in the amniotic fluid in proportion to the degree of fetal distress and low Apgar scores. It is well established that the opioid receptor ligands β-endorphin and enkephalin act on nerve cell ion channels and on the second messenger adenosine 5′-triphosphate energy production. It is also clearly stated in the opioid hormone literature that the opioid antagonists naloxone and naltrexone block opioid receptors and are effective in preventing nerve cell damage and vascular shock after brain and spinal cord trauma. Opioid antagonists should have high therapeutic potential for prevention of fetal brain ischemia resulting from stress-induced hyperendorphinemia.

DR. PARER (Closing). The incidence of cerebral palsy due to intrapartum asphyxia is, I think, <10%. Of course, an important feature of that other 90% to 95% of cerebral palsy is that by and large there isn't much we can do about it. But certainly intrapartum asphyxia leading to cerebral palsy is a potentially recognizable and avoidable cause, and therefore I think it needs to be examined thoroughly.

Dr. Goodlin, your knowledge of the literature is unparalleled in any obstetrician that I know in the world, and I must say I did not reread Claude Bernard to find his discussion of the subject 100 years ago.

One of the problems about the use of drugs to limit asphyxial damage in the past is that there hasn't been a good model by which to study it. As far as I know, the first large fetal model that we have available to study the effects of drugs on modifying damage has only been available for several years now, and that is a model that was developed in New Zealand, whereby the fetal carotid arteries are reversibly occluded.[1] One can produce brain damage in such a fetus that is quite reproducible. Unfortunately, this is almost total ischemia and thus not similar to the clinical situation. We have developed a complicated model, whereby we decrease uterine blood flow and produce hypoxia in the mother as well.[2] Unfortunately it is not as reproducible as the carotid occlusion model, but it is more like the clinical situation.

I will say nothing more about the suggestion of using atropine to abolish certain bradycardias because it has been discussed at great length in the past. I still disagree with its use.

Dr. Caillouette has presented a case to us. I do not know that the drugs I mentioned would help in such a case. However, many of us are using tocolytics such as terbutaline to decrease uterine activity while we are preparing a woman for cesarean section, so possibly these drugs could be useful as a short-term measure in a case such as that.

Dr. Kimball mentioned endogenous opioids and the possibility of blocking them. We have studied endogenous opioids in the fetus, but mainly from the point of view of their effect on blood flow. It seems that the endogenous opioids are part of a push-pull mechanism whereby blood flow to the kidney is maintained and blood flow to the muscle is balanced appropriately by the other vasoconstrictors. We have studied the use of naloxone and have some concerns about its use in the stressed fetus.[3] Of course, in the adult the idea of using the blockade is to elevate blood pressure and to maintain cardiovascular function. I do not know whether this is efficacious in the fetus.

Ovarian response in superovulated cycles after suppression with oral contraceptive steroids

Kenneth A. Burry, MD, Laura H. Greenberg, MD, and Phillip E. Patton, MD
Portland, Oregon

The endocrine response to controlled ovarian hyperstimulation was reviewed in 94 women undergoing in vitro fertilization during 114 cycles. The purpose of this review was to evaluate the effect of short-term oral contraceptive suppression on the recovery of pituitary gonadotropin function and subsequent controlled ovarian hyperstimulation. Seventy-three cycles (64%) were adequate for oocyte retrieval. In 41 cycles (36%) hyperstimulation was discontinued. The serum 17β-estradiol value in women with a poor response was 57 ± 50 pg/ml on day 8 compared with 376 ± 334 pg/ml in the women who completed in vitro fertilization ($p < 0.05$). The majority of women (84.2%) had a prompt response to controlled ovarian hyperstimulation after short-term oral contraceptive suppression. Most discontinuations were due to dominant follicle selection or luteinizing hormone surge and not to oversuppression by short-term oral contraceptives. Clinical pregnancies occurred in 15 women (20.5% of harvests). (AM J OBSTET GYNECOL 1991;164:1592-6.)

Key words: Contraceptive suppression of gonadotropins, programmed ovarian hyperstimulation

Controlled ovarian hyperstimulation protocols used for in vitro fertilization (IVF) and gamete intrafallopian transfer have used clomiphene citrate and human menopausal gonadotropins. Undesirable responses to ovarian hyperstimulation have included low estradiol response, dominant follicle development, and endogenous luteinizing hormone (LH) surge.

Oral contraceptive steroids have been used successfully for pituitary suppression of endogenous gonadotropins before controlled ovarian hyperstimulation protocols for IVF.[1-3] Gonadotropin suppression before ovulation induction allows scheduling of patients at preselected start dates for ovarian stimulation and results in a more predictable follicular recruitment length and oocyte retrieval time. A potential disadvantage of contraceptive steroid suppression is a poor response to human menopausal gonadotropin therapy.[4] The poor response is presumed to be secondary to the pronounced suppression of pituitary gonadotropins. Alternatively, a failure to adequately suppress endogenous gonadotropins may result in poor follicular recruitment or the occurrence of a spontaneous LH surge.

This article reports on an experience with the use of short-term contraceptive steroid suppression before ovarian hyperstimulation and on the clinical outcomes during IVF and gamete intrafallopian transfer. Recovery of ovarian function was monitored before and during controlled ovarian hyperstimulation.

Material and methods

Ninety-four women were evaluated in a total of 114 cycles of suppression and hyperstimulation. All women were suppressed with a daily dose of 35 μg ethinyl estradiol and 0.5 mg norethindrone (Modicon, Ortho Pharmaceutical Corp., Raritan, N.J.), beginning on day 5 of the menstrual cycle preceding IVF on gamete intrafallopian transfer. The mean duration of suppression was 34 ± 2 days. Suppression continued until the predetermined start date of controlled ovarian hyperstimulation, which was accomplished with either a combination of 100 mg clomiphene citrate (Serophene, Serono Laboratories, Inc., Randolph, Mass.) and 75 IU human menopausal gonadotropins (Pergonal, Serono) or 225 IU human menopausal gonadotropins beginning day 3 after withdrawal of contraceptive steroids.

After 5 days of stimulation the follicular response was measured by serum 17β-estradiol and pelvic ultrasonography every 1 or 2 days, depending on follicular response. When the 17β-estradiol level was ≥500 pg/ml, serum samples for progesterone and LH were also measured. When the serum 17β-estradiol level was ≥750 pg/ml with at least two follicles >16 mm in mean diameter, 4000 IU human chorionic gonadotropin

6/6/28668

(hCG) was administered intramuscularly. Oocyte retrieval was done by laparoscopy or an ultrasonographically guided transvaginal approach approximately 34 hours after the hCG injection. Supplemental hCG (1000 IU) was administered on the day of oocyte retrieval and then every 48 hours for a total of five additional doses. A cycle was canceled if a dominant follicle was noted on ultrasonographic examination, if the 17β-estradiol level was too low (<100 pg/ml) on day 8, or if LH surge activity (a twofold rise over the previous value or a level ≥25 mIU/ml) was detected.

In 33 of the 114 cycles additional sera were obtained on cycle days 1, 3, 5, and 7. These sera were later analyzed for estrone, 17β-estradiol, androstenedione, and bioactive LH. Steroid assays were performed by standard radioimmunoassay techniques. Bioactive LH was measured by a Leydig cell assay.[5] Statistical analysis was performed with Student's *t* test, Duncan's multiple range test, and analysis of variance with StatPak (Northwest Analytical, Inc., Portland, Ore.). Stepwise discriminant analyses were done with the SPSS-X software version 2.2 (SPSS-X, Chicago).

Results

Of the 114 cycles initiated, 41 (36%) were canceled because of a poor 17β-estradiol response (18 women, 15.8%), a dominant follicle (13 women, 11.4%), or an LH surge (7 women, 6.1%). Three cycles were cancelled for miscellaneous reasons. In nine additional women an LH surge was detected in serum samples drawn just before administration of hCG (Table I).

Patient age, length of contraceptive steroid suppression, hyperstimulation protocol, and the time of hCG administration in those women who received it were compared between the group with canceled cycles and the group with retrieval cycles. There were no significant differences between these two groups, except for the difference in 17β-estradiol after 5 days of hyperstimulation, 57 ± 50 versus 376 ± 334 pg/ml (Table II).

Serum progesterone values were significantly greater ($p < 0.05$) in women in whom an LH surge was demonstrated at the time of hCG administration, 1.77 ± 0.18 versus 0.66 ± 0.08 ng/ml. There was a trend toward an elevated progesterone level in these women 14 hours earlier, 0.91 ± 0.1 versus 0.66 ± 0.08 ng/ml. Therefore progesterone was not predictive of an impending LH surge in a timely manner within a clinical setting. One of the nine women with oocyte retrieval after an LH surge did have a clinical pregnancy.

Hormone profiles of the 33-cycle subgroup that had serum sampled on days 1, 3, 5, and 7 revealed an early return of estradiol and LH after oral contraceptive suppression. Twenty-two cycles had a normal response, including six women who experienced an LH surge. The other 11 women had a low estradiol response ($n = 7$) or a dominant follicle ($n = 4$). There was a significant increase ($p < 0.05$) in 17β-estradiol and LH by day 3. There was a significant difference ($p < 0.05$) in estradiol values on day 1 in women with a dominant follicle and on day 7 in women with a low estradiol response (Table III). There were no significant differences between the normal and low estradiol responders for any of the other hormones evaluated (Table IV).

Of the 73 cycles that resulted in oocyte retrieval, 15 resulted in clinical pregnancies (20.5%). Three pregnancies occurred in women whose cycles were canceled (7.3%).

Table I. Outcome of ovarian suppression with oral contraceptive therapy

No. of cycles	114
No. of patients	94
Mean age of patients (yr)	34 ± 1
Mean duration of suppression (days)	34 ± 2
No. of cancelled cycles	41 (36%)
No. of retrievals	73 (64%)
No. of LH surges	16 (14%)
Mean duration of induction (days)	11.9 ± 0.3
Pregnancies/cancelled cycle	3/41 (7.3%)
Pregnancies/retrieval	15/73 (20.5%)

Table II. Estradiol (picograms per milliliter) after 5 days of stimulation

Low responders ($n = 18$)	57 ± 50*
Normal responders ($n = 73$)	376 ± 334
No short-term oral contraceptive suppression ($n = 5$)	313 ± 290

*Difference between other two groups, $p < 0.05$.

Comment

Suppression of the pituitary gonadal axis with oral contraceptive steroids does assist in the scheduling of oocyte retrieval in some IVF and gamete intrafallopian transfer centers. There is concern that the use of these agents can suppress the ovarian response to hyperstimulation.[4] Our data from 114 cycles with use of a low-dose oral contraceptive demonstrates that in most women the ovary responds rapidly to exogenous gonadotropins. Most of the women had a return of normal pituitary and ovarian hormonal milieu within 3 days of cessation of suppressive therapy. Sampling of serum estrone, 17β-estradiol, androstenedione, and bioactive LH obtained shortly after withdrawal of oral contraceptives was not helpful in predicting the subsequent response of ovarian hyperstimulation. Basal estrone and 17β-estradiol values were not predictive of

subsequent response to hyperstimulation protocols, except in women who had a dominant follicle. Women with a dominant follicle most likely had incomplete suppression with the oral contraceptive used in this study. Basal levels of androstenedione and bioactive LH were not predictive of poor or inappropriate response to hyperstimulation, as was previously described by Fenichel et al.[6]

In our series 36% of cycles initiated were canceled. The experience with contraceptive steroid suppression in women with canceled cycles was that the majority of canceled cycles were due not to a poor 17β-estradiol response but rather to either dominant follicle selection or an LH surge. In 16 of the 114 cycles a premature LH surge was observed and was the reason for cancelling the cycle in 7 women. Nine others had an LH surge and had an oocyte retrieval. There was one pregnancy in this group (11%) as compared with 14 pregnancies (21.9%) among the other 64 women who did not have a surge.

Despite careful monitoring of endocrine parameters, even twice a day, this study was unable to predict ovarian response to hyperstimulation or an LH surge in a timely manner in a clinical setting. Other studies have suggested that follicle-stimulating hormone before ovarian hyperstimulation may be a predictor of outcome.[7] Follicle-stimulating hormone was not evaluated in this study.

Dominant follicle selection and LH surge are not the result of pituitary suppression. A poor 17β-estradiol response may be due to the persistent suppressive effects of contraceptive steroids. This was evidently the case when a higher dose of norethindrone (1 mg) was used by Benadira et al.[4] A low-dose pill was used in the present study, 0.5 mg norethindrone and 35 μg ethinyl estradiol. The lower progestin dose may explain the difference in postpill suppression. A recent experience with a higher-dose oral contraceptive (1 mg ethynodiol diacetate and 50 μg ethinyl estradiol; Demulen, G.D. Searle & Co., Chicago) has resulted in prevention of spontaneous LH surges.[8] The women in this study had an excellent response to hyperstimulation and a low cancellation rate. Possibly a higher estrogen dose was responsible for the different experience in LH surges compared with the present study. A conception delay after contraceptive use has been reported, with a difference in fertility related to the estrogen dose of the contraceptive steroid used.[9]

Suppression with a gonadotropin-releasing hormone (GnRH) analog resulted in a more desirable ovarian response in women with a previous dominant follicle or LH surge.[10, 11] A major disadvantage has been the increased amount of menotropins required to induce an adequate follicular response.[12] Women with GnRH analog suppression require approximately 10 ampules more human menopausal gonadotropin.[13] However, if the cancellation rate is significantly <36%, it would be cost-effective to use GnRH analogs to down regulate pituitary gonadotropins in programming cycles for hyperstimulation. If pituitary suppression were prolonged after contraceptive steroid suppression, then the results should have been similar to GnRH analog suppression. This was obviously not the case with the low-estrogen-dose pills but may explain the better experience with the 50 μg ethinyl estradiol–containing pill.

Because of the high cycle cancellation rate in women with contraceptive steroid suppression, we have used 1 mg/day leuprolide acetate subcutaneously beginning 2 weeks before ovarian hyperstimulation and continuing until hCG is administered. In a preliminary group of 38 women the cancellation rate has declined to 13%, all of which was due to a poor 17β-estradiol response. Outcomes were good, resulting in a 26% clinical pregnancy rate. Others have reported the use of GnRH analogs to lower endogenous LH and have observed a higher rate of live births.[14]

The expense of leuprolide acetate and additional human menopausal gonadotropin required for ovarian hyperstimulation is prohibitive for many women. There have been varied experiences with contraceptive steroid suppression before IVF. A study comparing the performance of different doses would be worthwhile because it may be a more cost-effective method of ovarian suppression than GnRH.

In summary, the majority of women (84.2%) had a prompt return of pituitary and ovarian function after oral contraceptive therapy. A cancellation rate of 36% is not acceptable when compared with suppression with GnRH analogs (13%). However, the majority of cancellations were due to a dominant follicle or an LH surge. The cancellation rate resulting from a poor 17β-estradiol response was similar to that of leuprolide acetate, 15.8% versus 13%.

Discussion

DR. LEON R. SPADONI, Seattle, Washington. During the past decade IVF and its progeny, gamete intrafallopian transfer, zygote intrafallopian transfer, and SOURCE (superovulation and uterine replacement of capacitated enhanced semen), to mention just a few, have captured the imagination of the medical community, infertile couples, and the media. Despite tremendous improvements in stimulation protocols, oocyte retrieval, and embryo culture, the relatively low pregnancy rate and high cost per cycle has prevented this procedure from becoming more widely available to couples who have no other avenues for achieving a pregnancy.

Dr. Burry has described a protocol for pituitary suppression of endogenous gonadotropins before controlled ovarian hyperstimulation by means of low-dose oral contraceptive steroids. The purpose of gonadotropin suppression before ovulation induction allows scheduling of patients for ovarian stimulation at preselected start times, which hopefully will result in a more predictable follicular recruitment length and oocyte retrieval time. Although this article demonstrated that short-term suppression of endogenous gonadotropins with low-dose oral contraceptives was effective in terms of a 21.9% pregnancy rate, the 36% cycle cancellation rate was found to be unacceptable. The majority of the canceled cycles were due to a dominant follicle selection, an LH surge, or a poor estrogen response. Whenever a cycle is canceled, this becomes wasted effort in terms of patient cost, time spent by the IVF team, and emotional toll on the patient. Because of the high cycle cancellation rate in patients with low-dose contraceptive steroid suppression, the authors have discontinued the described protocol and have shifted to suppression of endogenous gonadotropins with a GnRH analog. This has resulted in a more desirable ovarian response in women with a previous dominant follicle or spontaneous LH surge. Their experience with this approach has been a decrease in the cancellation rate to 13% and a clinical pregnancy rate of 26%.

Dr. Burry has appropriately brought to our attention that this results in an increased cost per cycle as a result of the increased number of ampules of menotropins that are required plus the cost of the GnRH analog. The authors should be congratulated in their attempts to find ways of decreasing cycle cost, a trend that is badly needed to help curtail the burgeoning health care costs in our society. I would encourage them to continue their research with other doses of oral contraceptives in hope of decreasing the cycle cancellation rate and still obtaining an acceptable pregnancy rate.

I would like to ask the following questions. Would you define what you mean by a dominant follicle and explain why the cycle is canceled when this occurs? Can you give us an estimate of the increased cost of using a GnRH analog for gonadotropin suppression versus oral contraceptives? With the renewed interest in using natural cycles versus controlled ovarian hyperstimulation, what impact will this have on IVF in regard to cost and pregnancy rate?

Dr. Mary Martin, San Francisco, California. You implied that using oral contraceptives might lead to a suppression of the LH surge in the following cycle. Would you clarify what you think the mechanism might be?

One of our goals since starting our IVF program has been to avoid weekend retrievals. However, using individualized monitoring produces sufficient outliers that we have been remarkably unsuccessful in meeting this goal. I wondered how successful your regimen was with regard to obtaining a predictable retrieval day.

Dr. Burry (Closing). Dr. Spadoni, a dominant follicle is one that, by ultrasonographic parameters, is mature at the first scan. If after 5 days of stimulation we saw a single follicle that was 16 to 18 mm, we considered it dominant.

The increase in cost of GnRH over oral contraceptive suppression is at least $600, often $1000. There is a significant cost increase when menopausal gonadotropins are used, an average of 10 ampules of Pergonal in addition to the cost of the leuprolide acetate, 0.5 mg subcutaneously daily (Lupron, TAP Pharmaceuticals, North Chicago).

We are doing single egg retrievals in completely natural cycles and were initially very optimistic about this method. We do start people in natural cycles who have had poor response to leuprolide and high doses of Pergonal. Our cryopreservation program, though, has been very successful. We have a 20% continuing pregnancy rate as a result of cryopreservation. Many of our couples are electing to use the more aggressive stimulation so they can take advantage of multiple cycles of embryo transfer.

Dr. Martin, I did imply a suppression of the LH surge by using a contraceptive before stimulation. That was not something that I had anticipated. It was brought to my attention in a recent article by Gonen et al.[1] I was intrigued that they had absolutely no surges in a fairly large group of patients who had suppression with Demulen, one tablet daily. In natural cycles before this regimen was used, patients had a 15% to 16% rate of LH surges, a rate consistent with most other programs. As far as mechanism, anyone's guess is as good as mine.

Our success in avoiding weekends was quite good when we were dealing with small groups of patients. Initially, we treated patients in groups of five, and it would take us a while to have five who could afford IVF. We were very successful in midweek retrievals and transfers, so that the only thing we had to do on weekends was monitor gonadotropins and do ultrasonographic examinations. Now that our program is larger, we are working more weekends.

Significance of oligohydramnios complicating pregnancy

Lewis Shenker, MD, Kathryn L. Reed, MD, Caroline F. Anderson, RDMS, and
Nydia A. Borjon, RDMS
Tucson, Arizona

Oligohydramnios is a serious complication of pregnancy that is associated with a poor perinatal outcome. Eighty pregnancies complicated by oligohydramnios constitute the basis for this retrospective study. Forty patients had premature rupture of the membranes; of these, outcomes were good in 25. Twelve of 14 fetuses with oligohydramnios and intrauterine growth retardation survived. None of the nine fetuses with severe renal anomalies lived. None of the twins with twin-twin transfusion and oligohydramnios survived. Six pregnancies with oligohydramnios and premature separation of the placenta were identified; all of these resulted in fetal or neonatal death during the second trimester. (AM J OBSTET GYNECOL 1991;164:1597-600.)

Key words: Oligohydramnios, premature rupture of membranes, renal anomalies, premature separation of the placenta

The accurate diagnosis of oligohydramnios became possible with the introduction of ultrasonographic examinations during pregnancy. Outcomes for this complication of pregnancy have been reported by several authors.[1-6] There is a consensus that severe oligohydramnios identified in the second trimester of pregnancy is an indication that perinatal outcome will be poor. Oligohydramnios may be associated with fetal anomalies, intrauterine growth retardation, and elevated perinatal mortality rates. The present paper investigates the causes for oligohydramnios and correlates the causes with outcome. A special group of second-trimester patients with both oligohydramnios and premature separation of the placenta is identified. The ultrasonographic and Doppler flow characteristics and differential diagnosis in patients with oligohydramnios and premature separation of the placenta are presented.

Material and methods

Fetal ultrasonographic studies performed at the Arizona Health Sciences Center Department of Obstetrics and Gynecology between January 1986 and June 1989 (8443 studies) were reviewed. Two-dimensional examinations were performed with 3.5 and 5 MHz transducers, and Doppler umbilical cord velocities were measured in selected patients. The diagnosis of oligohydramnios was made in 80 patients. Oligohydramnios was diagnosed when no pockets of amniotic fluid >1 cm were observed. The patients' charts were reviewed, and neonatal outcomes were recorded.

Table I. Causes of oligohydramnios

Cause		*No. of patients*	*Survived*
Premature rupture of membranes		40	25 (62%)
Intrauterine growth retardation		14	12 (84%)
Fetal renal anomalies		9	0
Renal agenesis	3		
Urethral obstruction	3		
Multicystic kidneys	3		
Premature separation of placenta		6	0
Twin-twin transfusion		3	0
Congenital anomalies (nonrenal)		2	0
Unknown		6	1 (18%)
TOTAL		80	38 (48%)

Results

The causes of oligohydramnios in our patients are summarized in Table I. The overall survival rate was 49%. Survival varied with the cause of oligohydramnios, from 84% in intrauterine growth retardation and 61% in premature rupture of the membranes to 0% in renal anomalies and premature separation of the placenta. Among those patients with premature rupture of the membranes, survival was related to gestational age at the time of rupture. At ≤25 weeks, only two of 15 babies survived (13%); after 25 weeks, 23 of 25 babies survived (92%).

The etiologic factors in growth retardation in our patients were hypertensive disorders in six, anomalies in two (Russell-Silver syndrome in 1, multiple malformations in another), and maternal drug use in two. Four patients had no identifiable risk factors. Doppler

Table II. Premature separation of the placenta and oligohydramnios

Case No.	*Age (yr)*	*Gravidity and parity*	*Onset of bleeding (wk)*	*Onset of oligohydramnios (wk)*	*Gestational age at delivery (wk)*	*Weight (gm)*	*Outcome*	*Remarks*
1	24	G3 P2	23	26	27	475	Stillborn	Doppler normal
2	35	G1 P0	10	23	27	320	Stillborn	Doppler systolic/diastolic high
3	23	G2 P1	?	20	29	1100	Death	Doppler normal
4	21	G4 P1	19	22	24	535	Death	Doppler normal
5	32	G4 P1	15	22	25	880	Death	Doppler normal
6	22	G4 P3	19	25	26	755	Stillborn	Doppler not done

G, Gravidity; *P*, parity.

umbilical cord flow studies were performed in all these patients. Systolic/diastolic ratios were high in eight, four of whom had absent diastolic flows. One fetus with absent diastolic flow was stillborn at 20 weeks' gestation. The other seven fetuses with high systolic/diastolic ratios or absent diastolic flows were delivered by cesarean section for fetal distress. Six fetuses had normal systolic/diastolic ratios; two of these were delivered by cesarean section for fetal distress.

In five of six cases, when premature separation of the placenta was diagnosed clinically and confirmed by ultrasonography, Doppler umbilical flow studies were performed. Four of the five studies were normal; one fetus had absent diastolic flow. The clinical features of the patients with oligohydramnios and premature separation of the placenta are summarized in Table II.

Comment

Causes of oligohydramnios in other studies[1,2] include spontaneous rupture of the membranes, intrauterine growth retardation, genitourinary anomalies, use of indomethacin in the treatment of premature labor[7] and abnormal karyotypes, including triploidy.[8]

The most common cause of oligohydramnios in this study is premature rupture of the membranes, and in a diagnostic plan membrane status (ruptured or intact) should be established initially. The quality of ultrasonographic examination is considerably reduced by the absence of fluid surrounding the fetus, and special care must be taken to identify fetal renal structures to exclude or establish the diagnosis of renal agenesis. Multicystic renal disease is less difficult to diagnose, because of the appearance of the kidneys and often the distended bladder on ultrasonographic examination. Oligohydramnios in twin gestation may be due to circulatory alterations, intrauterine growth retardation, or fetal death.

There have been several reports describing oligohydramnios accompanying intrauterine growth retardation. Hill et al.[9] used oligohydramnios as a screening tool for the diagnosis of intrauterine growth retardation. Philipson et al.[10] recognized that the presence of oligohydramnios should increase the clinical suspicion of growth retardation, but, if it is used as the only screening tool, 84% of cases would be missed. Steele et al.[11] suggested that four severely growth retarded infants with severe oligohydramnios had fetal renal failure. Severe oligohydramnios worsens the prognosis for survival in the growth retarded fetus; however, with active intervention 12 of 14 newborns in our series survived. Doppler umbilical flow studies with a high systolic/diastolic ratio were seen in fetuses who developed severe distress, as defined by positive contraction stress tests and fetal bradycardia. All of the viable fetuses with high ratios were delivered by cesarean section.

The early appearance of oligohydramnios in twin gestation is a very poor prognostic sign. In our three cases, all the fetuses were stillborn or died because of immaturity.

The six patients with oligohydramnios and premature separation of the placenta were of particular interest. Every attempt was made to be certain that ruptured membranes was not responsible for the oligohydramnios. Leakage of amniotic fluid could not be demonstrated in any of these patients despite multiple examinations. All patients spent several weeks in the hospital, and some received blood transfusions. All pregnancies ended in the second trimester with a uniformly lethal fetal outcome. Premature rupture of the membranes with severe oligohydramnios has been described as a risk factor for premature separation of the placenta.[12] In our cases the separation of the placenta preceded the appearance of oligohydramnios. In one study, two cases of antepartum hemorrhage were noted among 113 patients referred for fetal assessment because of oligohydramnios in the absence of ruptured membranes.[3] On that basis, active intervention for oligohydramnios when "perinatal salvage was considered feasible" was recommended. Delivery would have been inappropriate and not resulted in improved salvage in our six patients because of fetal immaturity. It is interesting to note that Doppler umbilical flow studies were normal in four of five patients with oligohydramnios and bleeding in the second trimester and were not helpful in the prediction of the adverse outcomes that occurred. This is in contrast to the outcomes in fetuses with oligohydramnios and intrauterine growth retardation. We speculate that inadequate placental function leading to inadequate fetal renal perfusion may be responsible for the oligohydramnios when premature separation of the placenta is present in the second trimester.

Discussion

DR. RUSSELL K. LAROS, JR., San Francisco, California. Dr. Shenker and colleagues have described their experience with 80 cases of severe oligohydramnios discovered during the second trimester of pregnancy. Appropriately, they analyzed the pregnancy outcomes with respect to the cause of the oligohydramnios. Clearly, the best survival (84%) was in the 14 cases of intrauterine growth retardation. The overall survival of 62% in the 40 patients with prolonged ruptured membranes is compatible with other reports in the literature. The authors stress the importance of gestational age at the time of rupture as a predictor of outcome.

The study group includes nine patients with renal anomalies. Three of these were cases of urethral obstruction. Our genetics group has been quite successful in treating cases such as this in utero with a current survival rate of 40% in 40 cases.[1] Both catheter drainage of the fetal bladder into the amniotic sac and intrauterine surgery have been accomplished successfully. Were any of your three cases appropriate candidates for surgery?

Dr. Shenker's experience includes three cases of twin-twin transfusion with the "stuck twin" phenomenon. This is a problem exclusive to monochorionic, diamniotic pregnancies.[2, 3] The Seattle group has reported significant improvement in outcome with serial amniocentesis (31% versus 80% mortality); we have had similar results at our institution.[4]

The most significant contribution of this study is the delineation of a previously unrecognized association between chronic abruptio placentae and oligohydramnios. It will be important for the authors and others to expand the numbers of these cases to document whether the dismal prognosis observed to date holds up with larger numbers. Incidentally, my genetics colleagues tell me that they have observed persistent oligohydramnios in association with subchorionic hemorrhage after chorionic villus sampling; again the prognosis was very poor.

Finally, I would like to spend a moment reviewing a plan of action for the clinician presented with a case of oligohydramnios in the second trimester of pregnancy. The first question is, are the membranes ruptured? In general, we do not feel it necessary to attempt injection of indigo carmine under these circumstances but accept the evidence gathered by several pelvic examinations, searching for evidence of amniotic fluid leakage. If the answer is "yes," the couple should be carefully counseled about survival data on the basis of the gestational age at rupture. It is particularly important, if possible, for the couple to be fully counseled and reach a decision to terminate while the opportunity is still available, i.e., before the twenty-fourth week.

If the membranes are not ruptured, a careful ultrasonographic evaluation (searching for fetal anomalies) should be carried out. We frequently will reconstitute the amniotic fluid with an infusion of saline solution. The couple is then counseled on the basis of the prognosis for the anomaly discovered. In general, we do not do percutaneous umbilical cord sampling for chromosome analysis because the yield is quite low. Regardless of whether the membranes are ruptured, it is exceedingly important to keep the 24-week time frame in mind, so that the couple can receive complete counseling and reach their decision while termination is still possible.

I congratulate Dr. Shenker and his colleagues on a fine study and particularly look forward to seeing more data on the group with chronic abruptio placentae.

DR. ROBERT C. GOODLIN, Denver, Colorado. Doing cesarean sections when Doppler studies are abnormal seems rather radical to me, unless diastolic flow is absent. Perhaps this was the case. Was any therapy used for oligohydramnios? In 1982 I presented some data to this society in which we used amnioinfusion and expanded the maternal plasma volume; we had cases in which the oligohydramnios was corrected.[1] In the last 2 years we have had three cases of chronic abruptio placentae, all starting before 20 weeks, and all developing oligohydramnios. We treated these patients with amnioinfusion, plasma volume expansion, and bed rest. All three went beyond 30 weeks' gestation. While the series is limited, I think there is some value in this form of therapy.

DR. E. PAUL KIRK, Portland, Oregon. Dr. Shenker, both your article and that of Dr. Platt illustrate a problem that seems to be facing us increasingly—incidental findings in second-trimester ultrasonographic examinations. Could you help me understand the natural history of retroplacental clot or the partial placental separation found by ultrasonography in the second trimester without the presence of clinical bleeding? The relative frequency with which this incidental finding is reported presents difficulty in counseling patients.

DR. LAWRENCE D. PLATT, Los Angeles, California. What were the criteria you used to diagnose oligohydramnios? Did you use the amniotic fluid index, the 1 cm pocket, or simply gestalt? Knowing the method used is important for others to be able to reproduce this important study.

One should not be surprised that Doppler studies would be normal with placental separation. Consider why Doppler velocimetry is abnormal in intrauterine growth retardation. At the microscopic level, there is obliteration of the tertiary stem villi and smaller numbers of vessels at the 50 to 100 μm size in the tertiary villi. However, there is no evidence of these abnormalities after placental separation.

DR. SHENKER (Closing). Dr. Laros, one of our patients with urethral obstruction was referred to your department for placement of a catheter in the distended bladder. The baby, unfortunately in the group of 60% with failure, survived 10 weeks after the procedure but then was delivered in Tucson and died of pulmonary hypoplasia. One other fetus with urethral obstruction was tapped, and the fluid never re-formed in the bladder, indicating severe renal malfunction. The third fetus was not considered a candidate for surgery.

None of our patients with "stuck twin" phenomenon was treated by amniocentesis. Published results indicate that amniocentesis is a reasonable approach, a 31% survival being better than our 0%.

Dr. Goodlin, I am sorry that I did not make it clear that no cesarean sections were done because of an abnormal Doppler study. These patients had cesarean section because of fetal distress, a diagnosis based on fetal bradycardia, abnormal monitoring patterns, or positive contraction stress tests. It is only now becoming clear that the abnormal Doppler patterns are warning signs that precede the need to do anything, usually by a week or two. More data about the time of appearance of abnormal Doppler flow studies in particular groups of patients will become available. The only therapy we used for premature separation of the placenta and oligohydramnios was bed rest. Since this was not sufficient to produce any survivors, I would be interested in seeing the results of amnioinfusion in these patients.

Dr. Kirk, our two patients with premature separation of the placenta and oligohydramnios had demonstrable clots and were bleeding externally. We have seen patients with subchorionic blood collections in pregnancy with reduced or normal amniotic fluid volumes; in that case our experience has been that the prognosis is fairly good if the bleeding remains minimal and is not accompanied by severe oligohydramnios.

Dr. Platt, in defining severe oligohydramnios we used the 1 cm pocket criterion. It was essentially impossible to identify any amniotic fluid in the patients constituting this series. I am familiar with your work on trying to quantitate indices for amniotic fluid volume. We too were not surprised at the Doppler findings and included that information in this report to emphasize that the value of Doppler flow studies, as I emphasized before, is in the particular groups of patients who do have placental disease.

Hormonal inhibition of the endometrium for resectoscopic endometrial ablation

Philip G. Brooks, MD,[a, b] **Scott P. Serden, MD,**[b] **and Irene Davos, MD**[b]
Los Angeles, California

Attempts at inhibiting the thickness and vascularity of the endometrium in preparation for endometrial ablation by using different types of hormones have been reported. To evaluate the effects of two different progestins, danazol, and leuprolide acetate on the endometrium, compared with the features of early proliferative endometrium, histologic studies were done for at least five patients treated with each hormone who then underwent resectoscopic endometrial ablation for treatment of abnormal uterine bleeding. Significant and at times dramatic differences among the treatment groups were found, with progestin-prepared endometrium being the least successful and leuprolide-prepared endometrium the most successful. In addition, the prolonged suppression provided for a period of time after the procedure by depot leuprolide is likely to help inhibit endometrial regeneration and provide even better long-term success of the procedure. (AM J OBSTET GYNECOL 1991;164:1601-8.)

Key words: Resectoscopic endometrial ablation, endometrial inhibition, endometrial histology, abnormal uterine bleeding, operative hysteroscopy

Ablation of the endometrium for management of abnormal uterine bleeding, with either a neodymium: yttrium-aluminum-garnet laser or a gynecologic resectoscope, has become a useful and important treatment option in gynecologic practice. The ideal goal is to achieve amenorrhea; however, this has been accomplished only 50% to 67% of the time.[1-4]

Because both laser and electrical energies have a limited depth of tissue penetration and thermal damage, it is obvious that attempts at inhibiting the thickness of the endometrium might improve the success rates of these procedures. To accomplish this, the use of progestins, antiestrogens (e.g., danazol, megesterol), and gonadotropin inhibitors (leuprolide, nafarelin) has been suggested.[5] Our early experience with these preparations suggested that the endometrial response to each drug grossly differed from that of the others.

This study was designed to evaluate histologically the response of the endometrium to the progestins medroxyprogesterone acetate and norethindrone, to danazol, and to a gonadotropin-releasing hormone agonist, leuprolide acetate, and to compare those effects with endometrium from days 4 to 8 of an untreated menstrual cycle.

Material and methods

Twenty-five women with abnormal uterine bleeding (excessively heavy periods with the passing of clots, gushing, or prolongation of heavy days of the period, with or without anemia) were evaluated by office hysteroscopy and directed biopsy to rule out polyps, myomas, or atypical endometrium. The median age of these patients was 43.5 years (range, 37 to 48). All were evaluated hematologically for blood dyscrasia and coagulation defects; these studies were negative. All patients had failed therapy by curettage and hormonal therapy (cyclic estrogens and/or progestins), according to a protocol approved by the investigational review board of Cedars-Sinai Medical Center, Los Angeles. None were perimenopausal or postmenopausal, none desired further fertility, and all consented to resectoscopic endometrial ablation. Preoperative preparation of the endometrium was provided with progestins (norethindrone or medroxyprogesterone acetate depot), danazol, or leuprolide acetate in a randomized fashion; five patients were included in each group. Resectoscopic endometrial ablation was performed 4 to 6 weeks after therapy was instituted in the treatment groups or on day 4 through 8 of an untreated menstrual cycle. All procedures were done with a gynecologic resectoscope (Karl Storz Endoscopy America, Inc., Los Angeles), size 24 Fr, with a 90-degree angle wire loop electrode. Electrical energy was provided by a Valleylab Force 2 electrosurgical generator (Valleylab, Inc., Boulder, Colo.), with a pure undamped (cutting) waveform at 110 W. The surgical technique involved shaving the endometrium from the cornual areas and the fundal surface down to the internal os to a depth of approximately 3 to 4 mm.

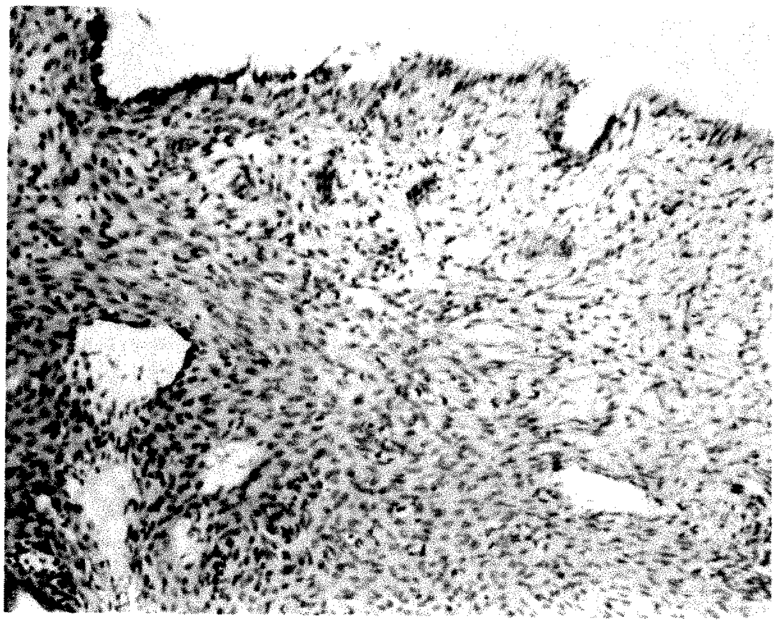

Fig. 1. Photomicrograph of endometrium after progestin therapy. Edema, angiectasia, and decidual reaction are notable.

All tissues were submitted in 10% formalin for histologic examination with hematoxylin and eosin, and special attention was given to the characteristics of the stroma, the glands, and the vessels and to the thickness of the endometrium. Some of the specimens were stained additionally with periodic acid–Schiff stain and with Masson's trichrome stain.

In addition to the above assessment, the depth of thermal damage was measured with a computerized two-point digitized method. A COHU (COHU Co., San Diego) black-and-white camera was attached to a COMPAQ DESK PRO 386/25e (COMPAQ, Houston) computer and Zeiss (Carl Zeiss Co., Thornwood, N.Y.) microscope. The program, IMAGE MEASURE 2500 IM (Microscience, Seattle), was used to assess the thermal effect on at least six representative sections of each case.

Protocols for preparation of endometrium

Progestins. Medroxyprogesterone acetate depot (Depo-Provera, The Upjohn Co., Kalamazoo), 200 mg intramuscularly, was administered for at least 6 weeks (but <9 weeks) or norethindrone acetate (Norlutate, Parke Davis, Morris Plains, N.J.), 5 mg daily, was given orally for at least 6 weeks before the ablation was performed. No additional therapy was attempted to control side effects such as breakthrough bleeding.

Danazol. Each of these patients received 600 or 800 mg (on basis of height and body weight) of danazol (Danocrine, Winthrop, New York) daily orally for at least 6 weeks before ablation procedures.

Depot leuprolide acetate. Because of the immediate gonadotropin-stimulating effect and the delayed inhibiting effect beginning approximately 10 to 14 days after injection,[6] 7.5 mg of depot leuprolide acetate (Depot Lupron, TAP Pharmaceuticals) was administered on about day 20 to 24 of an untreated menstrual cycle, and the ablation was performed between 4 and 5 weeks later.

Results

Progestin group. In a substantial number of cases the fluffy decidual character of the surface prevented adequate visualization, and often particles obstructed the outflow ports of the resectoscope sheath so that blunt or suction curettage was required before the ablation procedure was begun.

Histologically, there was diffuse edema of the endometrium. The stroma was thickened because of this edema and enlargement and deciduoid change of the cells. There was vascular proliferation and neovascularization, with the vessels having thicker and more dilated walls (angiectasia). Many areas showed increased secretory activity with the glands varying from secretory to tubular type. In none of the cases was the endometrium thin or atrophic (Fig. 1).

Danazol group. The overall suppressive effect of danazol was inconsistent. Some specimens were deciduoid, as with progestin therapy, and some were more atrophic, as with leuprolide (but not as intense), but in all cases the endometrium was relatively thick. The stroma was slightly edematous, and there was a greater variability in vascularity. Mild vascular proliferation and angiectasia were present in most specimens. The

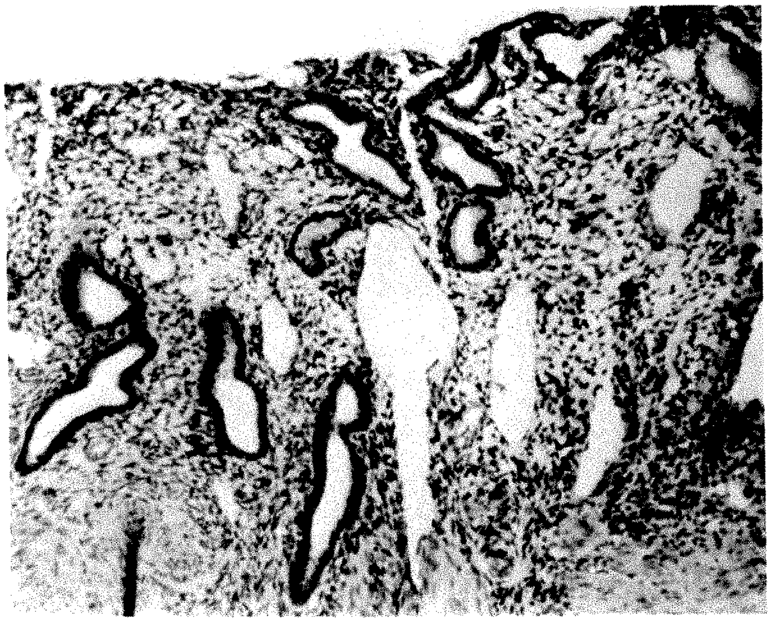

Fig. 2. Photomicrograph of endometrium after danazol therapy. Angiectasia is extensive and thickness is less than with progestins.

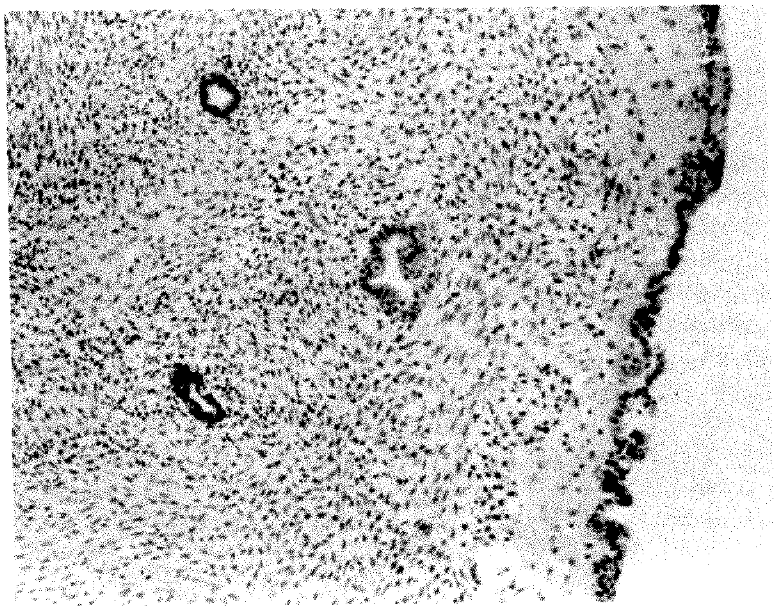

Fig. 3. Photomicrograph of endometrium after leuprolide therapy, showing atrophy, sparse glands, and dense stroma.

glands also exhibited significant variability, ranging from tubular and tortuous to mildly secretory in type but showing much dysynchrony with the stroma (Fig. 2).

Leuprolide group. In all cases the endometrium was thin and without any edema but not necessarily atrophic. The stroma had a spindle-cell-type appearance, not proliferative but more fibroblast-like, as though the cells themselves were thinned. The glands were either tubular or mildly tortuous and very reduced in numbers. Blood vessels also were reduced in number and size, but there was a slight amount of small vessel angiectasia (as contrasted to the large vessel angiectasia seen with progestin therapy) (Fig. 3).

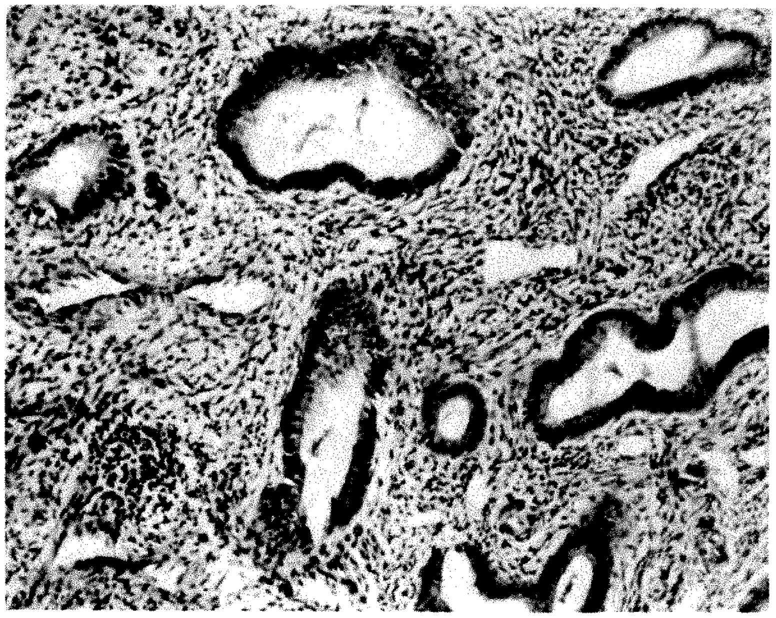

Fig. 4. Photomicrograph of endometrium on approximately day 6 of an untreated cycle, showing slight hyperplasia and mildly atypical vascularity.

Table I. Thermal damage to endometrium according to type of preparation

Type of preparation	*Mean thermal damage (μm)*	*Range of thermal damage (μm)*
Progestin	217	114-358
Danazol	175	89-300
Leuprolide	141	53-262

Untreated group, days 4 to 8. To our surprise, endometrium from the early proliferative phase in this group of patients was not the same as that seen in normal patients, as originally described by Noyes et al.[7] Although the gross appearance was that of thin, hypovascular endometrium, making the ablation very easy, histologically the tissue was dysfunctional appearing, that is, with glands and stroma being dysynchronous and with three of the specimens exhibiting a mild hyperplasia without atypia and with more spiral arterioles than expected (Fig. 4). (Is this the cause of the abnormal bleeding?)

Thermal damage. Measurements of the thermal damage revealed that the specimens pretreated with progestins had the greatest extent of thermal effect, with a mean depth of thermal damage of 217 μm, as contrasted with the mean damage in danazol-treated and leuprolide-treated tissue of 175 and 141 μm, respectively (Table I, Figs. 5 and 6).

Comment

Our experience confirms that resectoscopic endometrial ablation procedures are easier and faster when one has the luxury of time to prepare and suppress the endometrium. There is a significant difference, however, in the response of the endometrium to the different protocols that allege to suppress the endometrium.

Progestin therapy is the least successful in suppressing any of the elements studied (vessels, glands, stroma, thickness). Progestins, at least over a 6-week or 8-week period, minimally inhibit but markedly alter the endometrial histologic characteristics, with the most notable changes being the diffuse edema and vascular dilation and proliferation. It is our opinion that these changes explain why continuous progestin therapy for abnormal uterine bleeding so often fails.

Danazol works better than progestins to prepare the endometrium, but its undesirable androgenic side effects and inconsistent tissue effect, at least over the 6-week to 8-week period used in this study, make it less desirable than gonadotropin-releasing hormone agonists. Again, the breakthrough bleeding seen with danazol therapy may be explained by our observation that, in some patients, endometrial vascular angiectasia and a decidua-like reaction occurs.

Leuprolide acetate produces the most dependable suppression of all the methods tested. (Since this study was begun, this method of preparation has become our preferred method, and more than 25 additional cases have been evaluated, all with identical findings.) Although a single injection of the drug is believed not to induce castrate hormonal levels until 5 or 6 weeks after injection, our findings confirm that the early proliferative-type effect at 4 weeks after injection provides very adequate thinning of the endometrium,

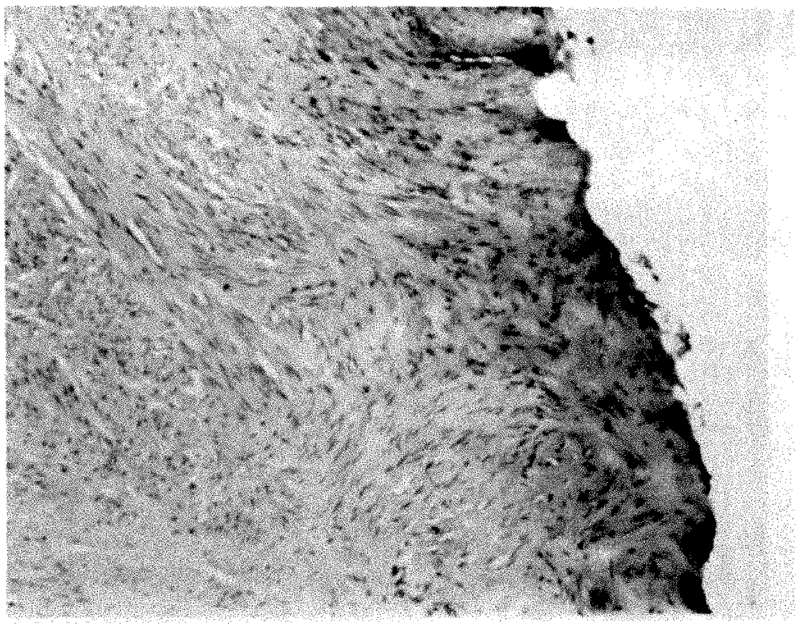

Fig. 5. Photomicrograph of endometrium showing thermal damage and the difficulty encountered in analyzing some of the tissue.

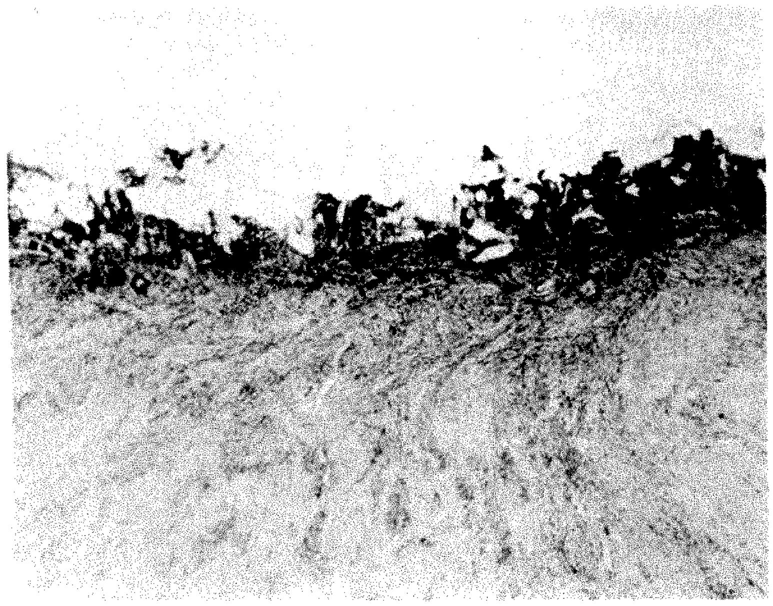

Fig. 6. Photomicrograph of endometrium after leuprolide therapy, showing extensive thermal damage.

along with inhibition of the vessels, glands, and stroma. In addition, the continual suppression that occurs for up to 2 weeks after the ablation is performed may be a very important adjunct by inhibiting regeneration of viable and responsive endometrial glands, very likely resulting in improvement in the amenorrhea rates and, ultimately, in the success of the treatment.

Performing endometrial ablations in the very early proliferative phase of the menstrual cycle is as easy and quick as in the patient prepared with gonadotropin-releasing hormone agonists. However, the lack of inhibition of endometrial regeneration after the procedure may make performing ablations during an untreated cycle less successful than in those using a preparation with a gonadotropin-releasing hormone agonist.

The exact significance of the thermal damage measurements is difficult to ascertain at this time. Of course, the knowledge of the very shallow amount of thermal damage in all of the specimens is very reassuring in that there is little risk of thermal damage to structures or organs adjacent to the uterus during these procedures. It is unclear as to why thermal damage is less in tissue with less vascularity and edema. One possible explanation is that the density and compactness of the tissue limits the depth of spread of thermal energy.

Finally, too little time has elapsed since performing these ablation procedures to comment on which method of endometrial suppression, if any, improves the amenorrhea rate the most. This will be the subject of a future study.

Discussion

Dr. David Pent, Phoenix, Arizona. The reawakening of interest in endometrial ablation, first by use of the laser and then by use of the resectoscope, has occurred within the past decade. During that time various authors have reported using a variety of medications to induce preoperative thinning of the endometrium, both to make the surgery technically less difficult and, more important, to improve the chances of success in the treatment of the patient. The two medications that have been used most frequently in the past are medroxyprogesterone and danazol, on the basis of their established track records of inducing the appropriate changes in the endometrium and endometriotic implants. The selection of which drug to use preoperatively seems to have been made on the basis of personal preference. Even in reported series that used more than one of the compounds, there was no effort to evaluate the immediate endometrial response or the long-term clinical response between the groups that had received the various preoperative medications. The one notable exception was a report earlier this year by Townsend et al.[1] In reporting on "rollerball" coagulation of the endometrium, they used three different regimens over a 4-week period to reduce endometrial thickness: danazol, ethinyl estradiol and levonorgestrel (Nordette), and medroxyprogesterone. It was thought that those patients who received danazol preoperatively had, in almost all cases, a very thin endometrium with no residual tissue. Half of the patients who received intramuscular medroxyprogesterone had a modest amount of endometrium that necessitated curettage, and histologic examination showed only a progesterone effect. Finally, the endometrium of those patients taking levonorgestrel and ethinyl estradiol was similar to the endometrium of patients who had been given medroxyprogesterone.

Dr. Brooks and his associates now present a similar study, which has been extended to include a gonadotropin-releasing hormone analog. The theoretical expectations for this compound are borne out by the histologic findings in the study, and, as Dr. Brooks indicated, that compound has become the preferred method of endometrial preparation before resectoscopic ablation of the endometrium. As he pointed out, the bottom line will be which method of endometrial suppression, regardless of the histologic picture at the time of surgery, gives the most satisfactory results with regard to amenorrhea or hypomenorrhea. In the meantime, however, it certainly is nice to have this well-designed study to provide a basis for the selection of the preoperative medication.

Dr. Brooks stated, as did almost all the others who have written on the procedure, that the "ideal goal is to achieve amenorrhea." It is true that for some patients amenorrhea is very definitely the desired end point because many of these early studies were performed on women who were extremely poor surgical risks, suffering from end-stage renal disease, leukemia, etc. In these patients total cessation of any blood loss was indeed critical. However, endometrial ablation is a procedure that appeals to women who do not want to be "cut," women who do not want a long postoperative recovery period, and those who, for various reasons, still want to preserve the uterus, including women who think that the motto of most gynecologists is "Don't take your womb to the tomb." These women, then, are seen with a complaint of hypermenorrhea, and the cure for that in their eyes does not necessarily mean amenorrhea. Some, possibly many of them, would prefer to have menstrual periods that are less in flow and duration than their normal periods had been, and so it seems that we need to recognize that hypomenorrhea might be a more meaningful end point than a surgically induced amenorrhea would be.

I would like to ask Dr. Brooks to share with us his thoughts about a concern raised by other investigators,[2] that the endometrial ablation techniques may result in cells being buried in the myometrium that later may undergo a neoplastic change and, because of their location, cannot express that change by the usual uterine bleeding. Also, Townsend et al. took some of the patients who had received medroxyprogesterone preoperatively and gave them a second injection postoperatively in the recovery room; they believed that it appeared to reduce the postoperative complaints of discharge and spotting, although they admit that the issue remains to be fully evaluated. Did you find that the use of the gonadotropin-releasing hormone agonist has resulted in any decrease in spotting and discharge postoperatively? Finally, you, along with many other authors, are concerned about the need to inhibit regeneration of viable and responsive endometrial glands to improve the amenorrhea rates and ultimately the success of the treatment. You stated in your article that this may be an important advantage of the gonadotropin-releasing hormone agonist and that the suppression continues for up to 2 weeks after ablation. Loffer[3] has questioned this role of possible endometrial regrowth, noting that there is no suggestion of any increase in menstrual flow as the postoperative period lengthens, which one would expect if regeneration were progressive. Would you please comment on that?

3. Loffer FD. Hysteroscopic endometrial ablation with the Nd:Yag laser using a nontouch technique. Obstet Gynecol 1987;69:679-82.

Dr. Simon R. Henderson, San Francisco, California. I agree with you that there is not much difference in the gross appearance of endometrium seen in the first part of the cycle and that seen with danazol treatment. My experience is with taking down septa and removing fibroids through the hysteroscope, not with endometrial ablation. I have found use of the first part of the cycle or danazol treatment to be equally good in these patients. In using the resectoscope for removing septa in patients with recurrent abortion and infertility, I bend the wire from 90 degrees to straight to facilitate taking the septum down in the plane of the uterine cavity. I do not actually resect any tissue except where I am cutting, and I get a very nice septal excision using this technique.

Dr. Brooks, which fluid do you use to distend the uterus?

Dr. Kenneth A. Burry, Portland, Oregon. This technique is being offered to patients with perimenopausal bleeding. We now have gonadotropin-releasing hormone analogs that can cause amenorrhea and maybe better conversion of the endometrium. Dr. Brooks, do you think it is time to look at another medical approach, such as 3 months of leuprolide acetate to see what the bleeding pattern is going to be? The patients not too far from menopause may have a better bleeding pattern with just medical therapy over a short period of time until they do reach menopause.

Dr. Robert Israel, Los Angeles, California. Were there differences in the bleeding pattern and degree of abnormal bleeding among the patients in the four groups before their entry into the study? Were pretherapy endometrial biopsies performed?

Dr. Brooks (Closing). Dr. Pent, amenorrhea as the desirable goal is really something that we physicians have made up. Patients are exceedingly grateful for having lighter menstrual periods, for being able to go out of the house on those days that used to require bed rest. Our success rate in restoring menstrual periods to normal flow or better in about 140 endometrial ablations to date is about 92%. This is about the same success rate as reported for laser ablations.[1]

The question of burying cells and delaying detection of future carcinoma of the endometrium is a critical issue with which all of us who perform ablations, with either the resectoscope or the laser, have wrestled for a long time. The answer is not in yet. However, it is a general feeling that the problem is not as big as we had feared. First of all, in more than 15 years since the first ablation studies were reported, there has not been a single case of endometrial carcinoma reported in these patients. Second, to my knowledge, there has not been a single case of adenocarcinoma of the endometrium reported in patients who had previously had Asherman's syndrome. With Asherman's syndrome, not only is there obliteration of part of the cavity but there is an unresponsive, inhibited endometrium as well. Why then doesn't a uterus that has only 50% of the cavity obliterated not bleed at all with normal hormonal stimulation? I believe that an unresponsive endometrium also occurs from these ablation procedures, and this may be an environment in which adenocarcinoma might not develop.

Patients for whom this procedure fails to control bleeding all bleed externally. We know about it. The blood has access to the outside and we become aware that they are bleeding. Finally, both Goldrath[1] and I (unpublished observations) in our early experiences have found that the cavity is constricted, but not obliterated, by endometrial ablation. Goldrath has evidence from hysterosalpinography, and I have done hysteroscopy on 20 patients postoperatively. We both have found that the cavity is narrowed, more like a diethylstilbestrol cavity than like that with Asherman's syndrome. These women have a tubular endometrial cavity with a lining that consists of one cell layer of cuboidal epithelium, which is unresponsive to hormones. We believe that if bleeding is going to occur it probably will show up on the outside. Time will tell whether this is true, but I feel that hidden bleeding is something that we worry about more than we need to.

I have no evidence that one preoperative medication makes the postoperative spotting and discharge less than another. This drainage, or weeping of the endometrial tissue, is mostly a bloody discharge and not as offensive as that after cryosurgery of the cervix. I have not found that either the bleeding pattern in the first 3 months or the likelihood of resumption of periods has been substantially altered by any of the preparations. To date it is only theory that inhibition of the endometrium by the gonadotropin-releasing hormone analog for an additional couple of weeks may allow the scar tissue to predominate.

Dr. Henderson, the reason we started this study is that at hysteroscopy there is indeed a difference in the appearance of the endometrium when progestin, danazol, or leuprolide acetate is used. In fact, the increased vascularity and the friability are what prompted this investigation. Although this did not interfere with the ablation because the electrical current coagulated the vessels, I was convinced that I could distinguish a patient who had been prepared with progestin from one prepared with leuprolide acetate.

At first I, too, attempted to use the resectoscope for virtually everything. Indeed, it is easy to use. However, in treating septa and synechiae in an infertile or reproductive wastage patient, I avoid using anything that could increase scarring inside the uterus, unless it is necessary. I have gone back to using scissors since it is so simple and bloodless and scarring is minimal. By the way, you do not have to bend the wire loop since they now make a 0-degree wire loop. There is also a 0-degree pointed electrode that can be used as an incising knife.

The fluid used for all of these cases was 3% sorbitol, although glycine seems to be just as effective. Others have reported the use of Hyskon. I choose not to use Hyskon because I do not like the pictures I obtain through this medium nor do I like the stickiness and the need to rinse my equipment. Sorbitol, in a continuous flow system, is a very effective and useful medium and allows for the use of electrical energy under water.

Dr. Burry, endometrial ablation was done in some patients who cannot wait very long. Some of our patients do not go into the menopausal state until age 55 these days. I would be concerned about the safety of gonadotropin-releasing hormone analogs used, even intermittently, for such long periods of time. I do not believe there are good data yet on this question. However, it may very well be useful to try 3 months of a gonadotropin-releasing hormone analog and watch the bleeding pattern.

Dr. Israel, the bleeding patterns were fairly similar. All patients had previous dilation and curettage or hormones as treatment of excessive bleeding. We were on a very strict protocol at Cedars-Sinai because the use of the resectoscope was considered investigational. All patients had previously been treated for excessive bleeding. All had office hysteroscopy performed before the endometrial ablation to rule out myomas, polyps, or atypical endometrium.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1991 issues from the Publisher, at a cost of $61.00 for domestic, $88.27 for Canada, and $84.00 for international for Vol. 164 (January-June) and Vol. 165 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Vulvar vestibulitis: Prevalence and historic features in a general gynecologic practice population

Martha F. Goetsch, MD

Portland, Oregon

All gynecologic patients seen by the author during a 6-month period were questioned and examined by means of a swab test to determine the prevalence of vulvar vestibulitis and the normal variation in sensitivity of vestibular skin. Of 210 patients, 78 (37%) had some degree of positive testing. A total of 31 patients (15%) were found to fulfill the definition of vulvar vestibulitis. A questionnaire was administered to these patients as well as to seven patients in whom vestibulitis had been previously diagnosed. A total of 50% had always had pain, most since their teenage years. Their history was not suggestive of a cyclic or remittent pattern of symptoms. Those with secondary dyspareunia or resolution of pain were usually either in a post partum phase or had group B streptococcus or human papillomavirus. The two most severe cases of vestibulitis occurred after use of fluorouicil cream. A total of 32% had some female relative with dyspareunia or tampon intolerance, raising the issue of a genetic predisposition. (AM J OBSTET GYNECOL 1991;164:1609-16.)

Key words: Vulvar vestibulitis, dyspareunia, focal vulvitis

Vestibulitis is the name given to the problem experienced by women with painful introital skin in whom clinical confirmation is by demonstration of pain with light touch of a cotton-tipped swab. It has been described in recent medical literature as well as in old references, but there is no agreement as to cause.[1, 2] Prevalence data have not been published previously. This article attempts to establish prevalence in a general gynecologic practice as well as to define the spectrum of sensitivity of the vulvar vestibule. To elucidate symptoms and history, patients with vestibulitis were interviewed.

Methods

All gynecologic patients seen by the author in her private practice between July 1, 1989, and Dec. 31, 1989, comprise the study group. Patients were not included if they did not require a pelvic examination, were less than 3 months post partum, or were currently pregnant, although patients seen for follow-up 2 weeks after a first-trimester miscarriage or termination were included. Other patients excluded were those distraught for some reason (1), those inadvertently not questioned (2), and one 80-year-old patient whose status was post radiation and vaginectomy. Those patients who had repeat visits during the study period were entered only on the first visit.

Each study patient was asked the following question: "Do you notice now, or have there been times in the past when you have had pain at the opening of the vagina either in inserting a tampon or with sexual activity?"

Information was then gathered about each patient noting race, parity, and results of the swab test. The swab test was conducted at the sites noted in Fig. 1 with a water-moistened cotton-tipped swab. For reference, patients were asked whether touch at an adjacent site felt normal and not painful and were then asked to compare sensation at six points. The swab was rolled over the skin gently at each site, avoiding rubbing. Five grades of response were considered: 0, normal sensation; 1, unpleasant, scratchy sensation; 2, painful, sharp sensation; 3, patient acknowledged pain and was noted to flinch; 4, patient noted significant pain and recoiled. Patients' subjective answers provided the means for differentiating grades 0 to 2. The sites chosen for testing were intended to be representative but not inclusive.

A questionnaire was administered by telephone or in person by the author to survey those who were found to have vestibulitis during the study period. To this group were added the data from the same questionnaire administered to seven other patients in whom vestibulitis was diagnosed by the author before the study.

Vestibulitis was defined as the condition characterized by entry dyspareunia, pain experienced when inserting tampons, or pain with speculum insertion, cou-

From the Department of Ob-Gyn Education, Good Samaritan Hospital and Medical Center, and the Department of Obstetrics and Gynecology, Oregon Health Sciences University.

pled with sensitivity to touch with a swab in an aforementioned area of the vulvar vestibule. Borderline vestibulitis was a term used for the subjects who fulfilled the above criteria but denied having had to adjust sexual activity or tampon use.

Statistical significance of categoric variables was assessed with χ^2 analysis.

Results

During the 6-month study period 210 patients were entered in the study. All were white except for four who were black, and one each who was Native American, Hispanic, Chinese, and Japanese. Of those with vestibulitis, all were white except one patient who was Japanese and one Chinese patient who had borderline vestibulitis. Age distribution in the study group was 11 to 80 years.

Questioning revealed 43 subjects (20%) with symptoms of pain. Of these, all except three had positive swab tests, fulfilling the definition of either borderline vestibulitis (4%) or clinical vestibulitis (15% of the whole group) (Fig. 2). The three with negative swab testing had, in one case, a diagnosis of vaginismus after early sexual abuse, and, in two cases, no physical explanation for their complaints.

Of the remaining 167 subjects with no pain, 38 had positive swab test results at at least one site.

The likelihood of sensitivity at each site is compared in Fig. 3 for the group with vestibulitis. Patients with borderline vestibulitis or without symptoms had relatively lower percentages of positive sites but the order of sites likely to be tender remained the same: the area near each Bartholin's duct, the crypts adjacent to the urethra, the midline of the posterior fourchette, and finally the area of anterior epithelium between the urethra and clitoris. The degree of tenderness followed the same relative distribution as did the site prevalence, with most tenderness occurring in the paramedian rather than midline sites and more often posterior than anterior. In only three women were the paraurethral and anterior sites the most tender.

To explore what distinguished each subgroup, the data were separated into number of positive swab sites per patient and grade of most sensitive site per patient (Fig. 4). There was overlap between groups, and, although statistical significance was not achieved, the borderline group seemed distinguished from those without symptoms not by the severity of the worst site, but by number of positive sites. The difference between the vestibulitis group and women without symptoms was significant; 50% had five or six positive sites and had pain significant enough to cause flinching or recoil in reaction to the light swab touch.

Relationship to parity. The proportion of nullipara to parous women in the combined vestibulitis categories was significantly greater (55%) than that in the nonvestibulitis subjects (38% $p < 0.05$). More details emerged from the interviews.

In an attempt to clarify whether vestibulitis has a significant tendency to be episodic, answers were tabulated to the question of subjects having had previous vestibular pain. Of all subjects with no present complaint but recalling previous pain (25), four were nullipara, and only two described what may have been vestibulitis. Of the 21 parous subjects, all except five specified that the previous pain had been post partum rather than interval. Two of those five had had previous vestibulitis confirmed by the investigator. Thus, only four of 167 subjects (2%) without present vestibulitis had had prior vestibulitis excluding instances post partum, suggesting that aside from that circumstance it is not a recurring syndrome.

A history of having had post partum dyspareunia was associated with no greater likelihood of having a positive swab test; however, patients in whom post partum vestibulitis developed had a risk that it would become chronic, as shown by interview data.

Interview results of 38 subjects. Vestibulitis was diagnosed in 31 patients during the 6-month study period. This group was interviewed as were seven other patients in whom vestibulitis was diagnosed before the six months. Table I shows results of these interviews. The median age of subjects was 34 years and the median length of complaint was 8.5 years. If three patients are removed from the calculation who were known to have had postpartum vestibulitis resolve at 0.3, 0.9, and 2 years, the median length of complaint is 10 years. Half the respondents first noted pain on trying to use tampons, rather than during sexual activity. Twenty-eight women either avoid or restrict tampon use, and 14 noted that removal hurts more than insertion. Five patients described pain with sex but said they can use tampons without discomfort; only one has the converse situation.

Respondents were asked about their sexual relationships. Many admitted that they have reduced sexual activity because of pain unless their partner is female,

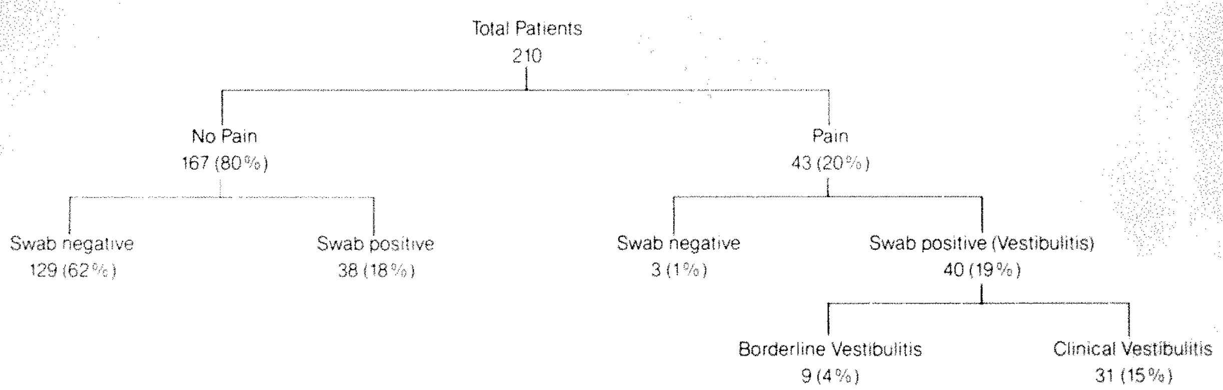

Fig. 2. Study population as it became segregated by categories of present complaints of pain and cotton swab testing.

but more than half thought that they and their partner had either come to an accomodation or that the problem was so minor that their relationship was not disturbed. At the other end of the spectrum, however, several subjects attributed failed relationships or significant stress to having vestibular pain. Often subjects wondered whether they were unique or had a hidden emotional aversion to sex. Even if they did not believe that the problem required significant intervention, a diagnosis and explanation helped both partners. It is noteworthy that half of the respondents had consulted a doctor; 37% had been told or had assumed that they were probably suffering from yeast infection.

The group was almost evenly split between those whose history was consistent with primary versus secondary vestibulitis. There was no difference in the amount of present pain and level of dysfunction described by those with primary as opposed to secondary vestibulitis. However, the average level of worst pain recalled in the past was greater for those with primary vestibulitis, usually being described as so severe as to make sexual relations impossible or even to cause continuous vulvar pain, whereas those with secondary development of sensitivity usually had continued some sexual activity even at their worst.

Of the 65% of subjects who noted variation in symptoms over time, most recalled gradual changes over months or years. The usual trend was that patients had lessening pain over time, although there were five with symptoms that were worsening; two of the five were perimenopausal and not taking estrogen. Thirteen other subjects had unchanging symptoms.

Obstetric history was noted, especially because there was a significant subgroup of patients (21%) with vestibulitis that started post partum and had not resolved. The entity known as postpartum dyspareunia fulfills the diagnostic criteria of vestibulitis. Vestibular pain was recalled by all patients delivered of infants by cesarean section. Post partum was commonly recalled as the time of worst vulvar pain by those with vestibulitis, but among multipara more than half noted relative differences, sometimes dramatic, in vestibular pain after different deliveries.

Histories of prior infection with human papillomavirus (HPV) are summarized in Table I and indicate that a majority of subjects with vestibulitis had no known association with this virus. The most significant correlation that could be found was that in patients with a positive HPV history, vestibulitis was much more likely to be a secondary condition rather than primary ($p < 0.05$). Colposcopic examinations were performed in only eight patients as dictated by severity because it was beyond the scope of the study to test routinely. Colposcopic evidence of HPV could only be found in one patient at the site of swab testing and she had had recent symptom resolution. Two patients who underwent surgical revision of the posterior vestibule did not have histologic evidence of HPV. Ironically, treatment for HPV with unusually large doses of fluoroucil cream (daily and immediately after lasing) had caused severe chemical burns in two patients and evolved into the most severe cases of vestibulitis seen in the study. One of those patients found that symptoms improved over 2½ years with an interval pregnancy, delivery, and lactation. The other had no improvement with trials of topical estrogen, locally injected dexamethasone, and topical lidocaine jelly over 1 year so underwent surgery with good although not complete relief. Two other patients had used fluoroucil cream without any affect on the vestibulitis.

The only infectious agent found to directly cause or worsen vestibulitis was group B streptococcus, noted in two patients. Although it was necessary to treat repeatedly, there was full resolution in one subject after 2 years of dyspareunia and reduction of pain in the other subject. Other patients who noted resolution were one with HPV cited in this article, one whose symptoms developed in the perimenopause and later resolved,

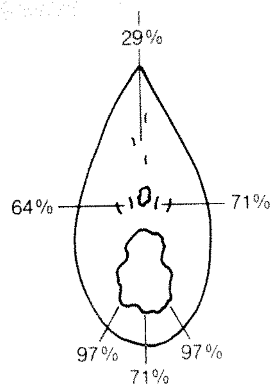

Fig. 3. Percentage of vestibulitis subjects positive at each swab test site (n = 31). All subjects tested positive at more than one site.

and three postpartum patients who had resolution while under observation after having had dyspareunia for 2 years, 11 months, and 4 months, respectively. Hormone status did not explain the continuation or the timing of resolution of vestibulitis in most postpartum patients.

One third of respondents knew of a female relative with dyspareunia or intolerance of tampons. Of those with sisters, this association was quite strong for those with primary vestibulitis (8 of 10) and not found among women with secondary vestibulitis. One subject asked each of 12 female cousins at a family reunion and found that all note tampon pain. Another patient deduced from family comments that there were four generations of women on her maternal side who had probably been affected.

Subjects were asked about possible autoimmune problems and one each had the following: Sjogren's and Raynaud's phenomenon, temporal arteritis, positive results from the Venereal Disease Research Laboratory with negative workup, and thyroid disease.

Two patients with vestibulitis were exposed to diethylstilbestrol, one with very extensive vaginal adenosis.

Comment

An entity fitting the description of vulvar vestibulitis was described a century ago according to Friedrich,[3] and was noted in textbooks of gynecology until the 1930s. References then disappeared from the literature until the 1980s when several reports reestablished its existence. In contrast to reports derived from referral practices of women who had significant complaints, this cross-sectional study of a general private practice elicited information which had usually not been volunteered by the subjects and revealed the prevalence of vestibulitis to be 15%. That such a high proportion of study subjects was found to fulfill the definition of vestibulitis was surprising. However, the swab testing also revealed that vestibular sensitivity describes a continuum from those with swab sensitivity but no pain, to those with tolerable borderline sensitivity, to those with significant dysfunction. It is important that the problem of pain was minor for many, and accomodation was aided even by getting an explanation of the problem. It nevertheless reemphasizes that sexual dysfunction is often underreported and underdiagnosed, indicating the importance of an astute clinician who feels comfortable routinely asking about sexual concerns.

Subjects in this study had a long median length of involvement, presenting a picture of sensitivity that predated sexual exposure in many cases, although data for that was not specific. That so many subjects noted problems in their teenage years raises the question of

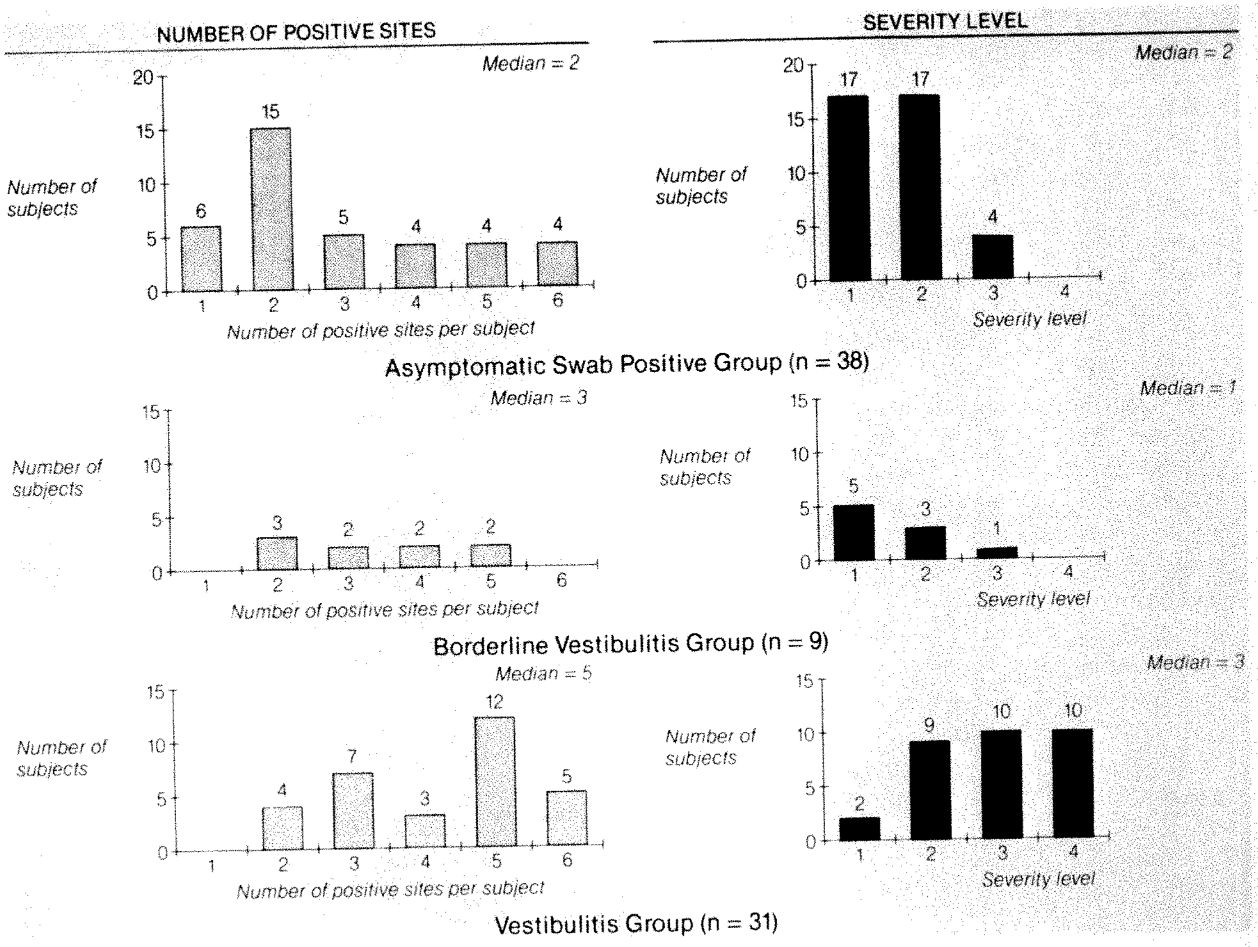

Fig. 4. Paired charts for each group illustrate (at left) the number of positive swab sites per subject and (at right) the severity of the most painful site per subject. Severity levels: 1, scratchy; 2, sharp; 3, evokes flinch; 4, evokes recoil. Statistical significance was present in comparing medians of subjects with vestibulitis with women without symptoms both for worst site ($p < 0.001$) and number of sites ($p < 0.001$).

there being a bimodal occurrence of vestibulitis (Table II), one group having it from early development and the other group, perhaps arising from those with greater sensitivity but no symptoms, noting it after an aggravating factor such as peripartum hormone changes or HPV infection. The data gathered here indicate that vestibulitis develops only in certain women when they are exposed to these factors. Some of the discrepancies in the literature with regard to HPV involvement[1-6] may be explained by this theory of acquired versus primary complaints. Woodruff and Parmley[7] reported that 27% of their group dated the onset of symptoms to the postpartum period, as did 21% in this study. Dyspareunia after delivery has not been identified previously as vestibulitis but fully satisfies the definition. A longitudinal study of postpartum patients is under way by the author.

Contrary to Peckham's findings,[2] spontaneous remissions were rare among patients in this study unless the vestibulitis had developed post partum. Were there to be a remission rate of 50% as Peckham suggested, the high prevalence rate found in this study would lead to the expectation of finding a large number of women who recalled past pain that had spontaneously resolved. This was not the case. The large proportion of subjects with primary vestibulitis in this study (50% in contrast to Peckham's 9%), strengthens the hypothesis that there is an inherent variation in sensitivity of the vulvar vestibule and that women may have vestibulitis with no antecedent irritant. The vestibule is the only genital tissue derived from endoderm[8] and may have unique developmental features.

Questions for future study would include clarification of any relationship such developmental influences as diethylstilbestrol or genetic markers such as HLA type might have to vestibulitis. Several findings that were anecdotal in this study should be investigated, such as whether family members really have vestibulitis by examination and whether a history of childhood sexual abuse influences later complaints. More studies are needed that test for unequivocal evidence of HPV and follow up results of topical or laser therapy. This may be particularly important in patients with acquired vestibulitis.

Unlike other studies, this one documented many patients with mild-to-moderate complaints. Treatment suggestions for most included continued use of artificial lubricant or use of 2% lidocaine jelly at tender sites before intercourse. Adequacy of 2% lidocaine therapy was not fully assessed. It could be that 5% lidocaine solution is more satisfactory in some patients. Surgery should be reserved for those with severe vestibulitis; other researchers have reported high rates of improvement or cure.[9]

Because the two worst cases of vestibulitis seen in this study occurred after greater than average use of fluorouracil cream, caution is warranted especially with regard to use after extensive lasing or without sufficient intervals between applications to allow recognition of chemical injury.

In conclusion, vestibulitis was found to have a prevalence of 15% in this general gynecologic population. Affected women could be divided by primary and secondary involvement, with postpartum factors, chemical burns, group B streptococcus, and HPV being implicated in secondary development of the syndrome. Half the subjects had adjusted satisfactorily to the discomfort, but vestibulitis remains an underdiagnosed problem with a confusing natural history.

Editors' note: This manuscript was revised after these discussions were presented.

Discussion

DR. CHARLES BROBERG, Pasadena, California. The patient with a problem of vulvar burning, itching, irritation, and dyspareunia has been the source of great frustration for me for years. I suspect that most of us have had more than one such patient who has left our offices as uncomfortable as when she entered, probably to seek a solution from another gynecologist. We followed our best judgment and tried many treatments. When we discovered an etiologic agent, the choice of treatment has been clear, but when no definite cause was found, our treatments tended to be empiric and often rather creative. Success has been inconsistent enough that no clearly best method has emerged.

Dr. Goetsch has undertaken a study of patients from her practice to determine the prevalence of the entity known a vulvar vestibulitis syndrome and to provide some standards for diagnosis and assessment of severity. A prevalence of 15% seems high for my practice, but perhaps if I asked more pointed questions or used the Q-tip more frequently I would discover I have been dealing only with the tip of the iceberg all these years. Because the literature has only recently begun to discuss this problem, she assures us that we are not alone in our frustration. It is reported that symptoms often improve or resolve completely with minimal or no treatment.[1] I hope this article will stimulate some good minds to discover a true cause and to suggest a reasonable therapy that will relieve those who suffer from persisting symptoms.

The term *vestibulitis* is of recent origin, but reports of various conditions of the vulva associated with pain or dyspareunia are not. In 1976 the term *erythematous vulvitis en plaques* appeared in the literature.[2] In 1983, obstruction of the Bartholin duct as a cause of pain with sexual activity was described.[3] The term *vestibular adenitis* attributed the symptoms to inflammation of minor vestibular glands.[4] The use of a cotton-tipped applicator to aid in diagnosis was suggested by Woodruff and Parmley[5] who reported success after surgical excision of the hymen and adjacent minor vestibular glands in 15 cases.[5] In 1985, we saw the term *vulvodynia* defined as the complaint of burning of the vulva without apparent cause.[6] In 1986 Peckham et al.[1] studied tissue blocks from excised surgical specimens and could find no correlation between the site of pain and inflamed minor vestibular glands. They suggested a new name, *focal vulvitis*. Eduard Friedrich[7] thought that term was too general and in February 1987 applied the currently popular term *vulvar vestibulitis syndrome*. This condition certainly is a syndrome rather than a disease because no consistent cause is known and the diagnosis is one made by excluding all known causes. In discussing the possible subsets of vulvodynia or vestibulitis we should also consider vulvar dermatoses, cyclic candidiasis, squamous papillomatosis, and inflammation of Bartholin's ducts.[8, 9] Dr. Goetsch adds three new terms, *borderline*, *primary*, and *secondary* vestibulitis.

I appreciate being reminded of our meager knowledge of this syndrome. If we clinicians continue to combine our experience, we should eventually do better in treating it. As a clinician I offer the following questions for Dr. Goetsch.

1. Because the symptoms described are similar to those of the lactating parturient who is hypoestrogenic and thus finds sexual activity uncomfortably dry, could topical estrogen therapy offer some help?

2. Because the use of antibiotics to treat coliform or streptococcus organisms found in vaginal cultures often make matters worse, it is helpful to use yogurt douches rather than antibiotics to ensure normal vaginal flora?

3. Is there any histologic feature of the mucosa of the posterior fourchette in the crescent between the Bartholin ducts that predisposes the patient to this syndrome?

4. You describe two cases of vestibulitis as a result of fluoroucil therapy as your worst cases. Inasmuch as the cause is known, do these cases properly belong in the report of an entity of unknown cause?

Dr. Donald H. Minkler, Berkeley, California. When I was a medical student at Harvard in the 1940s, endometriosis was thought to be a relatively rare condition. Then Dr. Joe Meigs at Massachusetts General Hospital began to put safety pins on endometriotic lesions in his surgical specimens so that the pathologists would not overlook them. Dr. Goetsch is similarly telling us that the prevalence of vestibulitis may not be recognized until the appropriate test is applied to all patients. I think her swab test is a useful contribution.

Dr. John A. Enbom, Corvallis, Oregon. One problem with this entity is that we are afraid to ask the question because we do not want the answer. Frequently the patient says somewhat timidly as she passes out the door, "By the way, I have had a problem for a long time but I have been afraid to discuss it." I am certain that these patients are more likely to discuss this with a female gynecologist than with a male.

Dr. Goetsch, in the group you classified as without symptoms, you had some patients who you considered to have positive swab test results. Have you repeated the test on these patients to determine whether this is a repetitive finding or an isolated finding on just that particular day?

Dr. Leroy S. Caspersen, Portland, Oregon. Surgical resection of the vestibular area is a treatment frequently advocated for this problem after the obvious specific causes have been excluded. This treatment adds a surgical scar with its inherent tenderness in a patient already suffering from dyspareunia. Although we are beginning to acknowledge a physical basis for this syndrome, there frequently is a psychologic overlay. I suggest psychologic counseling before undertaking the surgical approach.

Dr. Philip G. Brooks, Los Angeles, California. I have noted recently a tremendous enthusiasm by users of the colposcopic laser to diagnose HPV infections of the vulva and the vestibule. The diagnosis is usually made on the basis of one biopsy showing koilocytosis without any of the other marks of HPV and without either in situ hybridization or viral typing. The diagnosis of HPV has prompted some of these physicians to use surgery, laser, or topical fluoroucil, the last being obviously a very toxic treatment. Dr. Goetsch, in your patients who had concomitant or previous HPV infections, how was the diagnosis made? A diagnosis of HPV infection that is erroneous or merely coincidental should not be part of the vestibulitis syndrome.

Dr. Richard Marchik, Berkeley, California. The trouble is not with the diagnosis of this syndrome, it is with determining the right treatment. I do not think we have any good ones. The symptoms wax and wane almost without regard to what we do. If you wait long enough, most often the symptoms come back. Some people in our speciality have been overtreating this syndrome. In my community some have been very aggressive in the use of the laser to treat this entity by undermining the vaginal mucosa and bringing it down. They talk about all their cures, but I have some of their patients in my practice now who, a few months or years after surgery, have had recurrence of symptoms. By asking a good pathologist to go back and look at the slides, I have found that often the diagnosis of HPV was determined only on the basis of koilocytosis. My good pathologist will tell you that this is not sufficient to make the diagnosis of HPV. With hybridization of deoxyribonucleic acid, HPV cannot be found. The real challenge for us is to find a nonaggressive therapy that works.

Dr. Keith P. Russell, Los Angeles, California. We are all indebted to Dr. Goetsch for bringing the can opener to this picnic. Never have we in this society had so many authorities discussing their views on a subject. We all seem to agree that we are treating a disease but it is very hard to quantitate the symptoms. It seems to me that the diagnosis is made on the basis of the patient's reaction. Dr. Goetsch, in your study was there any attempt to correlate symptoms that morphologic changes such as thickening of Skene's glands or Bartholin's ducts, indicating prior infection?

Dr. Goetsch (Closing). Vulvar pain disorders have seemed a quagmire of complaints with many names and few clarifying characteristics. It is apparent, however, that vulvar vestibulitis does have distinguishing features that set it apart. I prefer to not consider this entity as a subset of vulvodynia because the patients in this study did not have constant pain as do those with vulvodynia. They were without pain except with coital entry or tampon insertion. They did not have chronic itching as do many patients with vulvar condylomata. When burning was the most prominent feature, it was post coital and not continuous with only one exception.

Dr. Broberg, you asked whether topical estrogen might help these patients. Evaluation of treatment was not the goal of this study, but I did look for a relationship of symptoms to hormone status. Neither development of nor worsening of symptoms correlated convincingly with the occurrence of menopause. Both patients with vestibulitis after high-dose fluouroucil treatment were given trials of topical estrogen cream with no improvement. I have a study under way in postpartum patients to determine the proportion in whom dyspareunia develops and which treatments help.

The only role I see for antibiotic treatment of vestibulitis is in the case of a specifically diagnosed problem such as group B streptococcus. Unlike reports of vulvodynia,[1] patients in this study did not relate worsening of symptoms to episodes of antibiotic therapy.

Woodruff and Parmley[2] pointed out that the vestibule is the area of the vulva most likely to react to irritants such as fluouroucil cream. This is also true of the milder irritation of vaginitis. Vaginitis, however, is not the cause of the vestibular pain. I think that these examples support the contention that this area has a greater tendency to become sensitive than does the adjacent vulva or the vagina. With no histologic explanation for the vestibule's heightened level of sensation, even in women without symptoms, I wonder whether it relates to the degree of innervation, something that might vary genetically.

You questioned whether the cases of fluouroucil injury belong in this discussion. I hope that we can increase our understanding of vestibulitis so that it is not considered to have an unknown cause. These two patients had initial chemical burns and tissue destruction, but ultimately they were left with vulvar vestibulitis.

Dr. Enbom asked whether I did repeated swab tests, especially in the group without symptoms. Early in my studies I checked patients a second time if they returned, and my impression was that the examinations varied by perhaps one level of response and by one in the number of positive sites. Because repeating examinations was cumbersome, I chose a cross-sectional design with a single examination for this report. The scale of responses used in this study is more detailed than necessary for clinical use. The women more likely to have symptoms were those with a broad surface area of tenderness, not those with a small spot that was quite painful.

Drs. Casperson and Marchik both express appropriate concern that surgery may be too hastily recommended. Most patients we see in practice have mild to moderate complaints and a large portion have no need for intervention. The application of lidocaine jelly to the vestibule before intercourse may be suggested. Specific causes such as group B streptococcus and obvious lesions of HPV should be treated. In my practice I have suggested surgery to only four patients. One declined, one early patient was treated with laser therapy, and the other two were treated with surgical revision of the fourchette and hymen. I resected only superficially, taking the skin but not resecting subcutaneous tissue or extending the incision down over the perineal body as described by Woodruff and Parmley.[2] This superficial skin revision can be done without scarring, although one must securely fix the edges of the defect during closure. If the incision pulls open and granulation tissue forms, the result may be as painful as the original problem.

I share Dr. Brooks' concern that HPV is overdiagnosed by histology alone. In this study, any patient with a history of treatment for cervical dysplasia, carcinoma in situ, or clinical condylomata were considered to have a presumptive diagnosis of HPV. A few patients did not meet these criteria. DNA hybridization tests were not used. My finding an association between secondary vestibulitis and a history of HPV-related disease points out the need for further investigation with accurate evidence for HPV at the sites of pain. I did note contradictory findings. Colposcopy on five of the nine patients who had both secondary symptoms and a history of HPV showed white epithelium at a site of the swab test in only one patient whose pain had now resolved. Therefore I have not treated any vestibulitis patient for HPV and believe we should be cautious in presuming a causal relationship.

Dr. Russell, I found few morphologic changes in the vestibule. These patients may have erythematous spots or bands of skin, but even these are subtle. The lack of morphologic change raises the question of whether the vestibule has a wider range of sensitivity than we had assumed. We are left with the quandary of whether the tenderness we find in some women represents a pathologic process.

Gliomatosis peritonei with malignant transformation: A case report and review of the literature

Gerald Shefren, MD, John Collin, MD, and Olive Soriero, MD, PhD
Mountain View, California

Gliomatosis peritonei is the implantation of glial tissue within the peritoneal cavity associated with ovarian teratomas. Previous reports have emphasized improved outcomes when these implants are found to be mature, even if the ovarian component is immature. A 16-year-old female with grade 3 immature teratoma was found on two subsequent laparotomies to have extensive peritoneal implantation of mature glial tissue. More than 5 years after the original surgery she was found to have a malignant abdominal glial neoplasm. This case illustrates a rare finding of malignant transformation of previously mature gliomatosis peritonei. (AM J OBSTET GYNECOL 1991;164:1617-21.)

Key words: Gliomatosis peritonei, immature teratoma, malignant transformation

Gliomatosis peritonei, defined as the implantation of mature neural tissue on surfaces of visceral or parietal peritoneum, usually in patients with ovarian teratoma, is a rare condition. Although the mechanism of implantation is unknown, it probably occurs most commonly from extrusion of mature glial tissue through capsular defects in the tumor[1] and is associated with teratomas of all grades. Despite often widespread involvement of peritoneal surfaces, gliomatosis peritonei is reported to impart an improved prognosis even in immature teratomas.[1, 2] A unique case is presented with mature (grade 0) glial implants documented both 10 and 22 months after the original diagnosis of grade 3 immature teratoma was made. Malignant transformation of these implants developed later. Previous reports of this phenomenon are reviewed.

Case report

A 16-year-old nulliparous female was admitted with abdominal pain and a large pelvic mass. At laparotomy there was a 20 cm, twisted left ovarian tumor with a 7 cm rupture in the capsule. A left salpingo-oophorectomy was performed. There were no obvious peritoneal implants noted; however, a staging laparotomy was not performed. The α-fetoprotein value was elevated at 557 ng/ml, while the β-subunit of human chorionic gonadotropin and chemistry values and chest x-ray film were normal. The tumor was reported as grade 3 immature teratoma.

The patient was treated with four cycles of cisplatin, vinblastine sulfate, and bleomycin and remained asymptomatic until 10 months after the original operation. At that time she was readmitted with acute, left lower quadrant pain. She had a large, tender cul-de-sac mass. Intravenous pyelogram, chest x-ray, and hematologic and chemistry values were normal. Test results for β-subunit of human chorionic gonadotropin and α-fetoprotein were negative. Laparotomy revealed a 10 × 6 × 5 cm cul-de-sac mass that was multilocular without excrescences. There were multiple peritoneal nodules from 2 mm to 2 cm in size over the bladder peritoneum, cul-de-sac peritoneum, posterior broad ligaments, uterosacral ligaments, and right fallopian tube. She underwent excision of the mass, pelvic and paraaortic lymphadenectomy, omentectomy, appendectomy, multiple peritoneal biopsies, including the diaphragms, for staging, and excision of multiple peritoneal nodules. The pathology report was of a mature teratoma with mature glial implants. No further therapy was given.

She was readmitted 22 months after the original laparotomy for removal of a grade 3 immature teratoma and 13 months after the second operation for removal of mature teratomatous tissue, with a new, right-sided 4 cm pelvic mass. Exploratory laparotomy showed a 4 × 5 cm, thick-walled, right ovarian cyst without excrescences. There were numerous small nodules <5 mm confined to the peritoneum of the small bowel, bladder, and rectosigmoid colon, but the upper abdomen was normal. The right ovarian cyst was removed and multiple biopsies of the pelvic nodules were done. The pathology report revealed a corpus luteum cyst and mature glial implants.

She underwent follow-up without additional therapy until 5½ years after the original operation, when she was readmitted because of increasing enlargement of a pelvic mass thought to be recurrent mature glial implants. The tumor markers β subunit of human chorionic gonadotropin, α-fetoprotein, and CA 125 all were normal. At operation there was acites, as well as

widespread metastatic seeding of the anterior abdominal peritoneum and the surfaces of the large and small bowel. The mass was a malignant tumor with glial differentiation infiltrating the abdominal wall muscuature.

The patient was treated with cisplatin, etoposide, and bleomycin for a total of four courses and later switched to VAC (vincristine, Actinomycin D, and Cytoxan). She showed no response to VAC and was later treated with palliative radiation to the anterior abdominal wall mass. She received further chemotherapy with BiCNU and 6-thioguanine. All therapy failed and she died of disease 7 years after the original diagnosis.

Pathologic findings. The original left ovarian tumor measured 17 × 15 × 9 cm and weighed 1020 gm. The tumor was solid and cystic, and the capsule was ruptured. Light microscopic sections showed a grade 3 immature teratoma with abundant immature mesenchymal elements, cartilage, and neuroepithelium (Fig. 1, *A* and *B*).

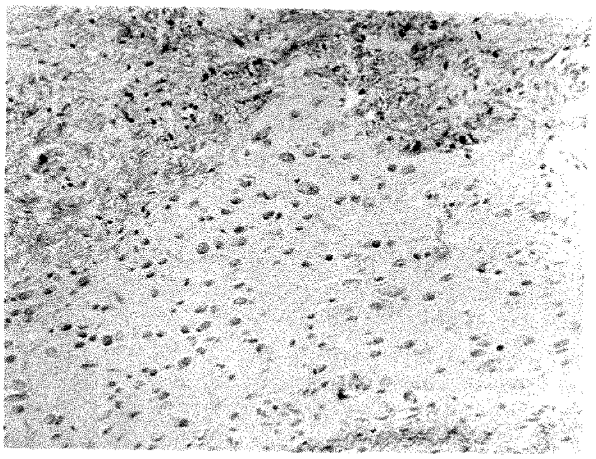

Fig. 2. Second laparotomy. Mature, grade 0 glial nodule, with scattered neurons. (Hematoxylin and eosin. Original magnification ×200.)

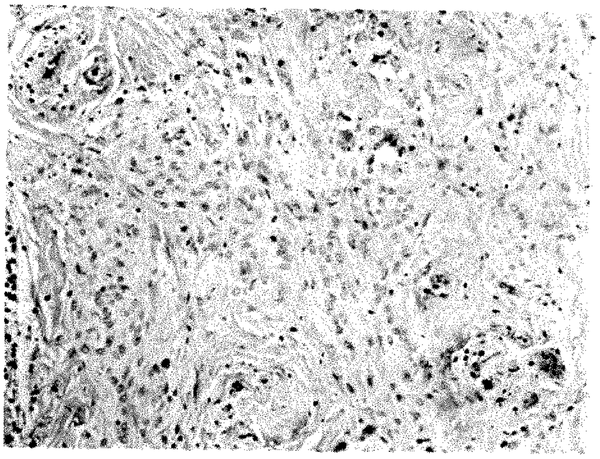

Fig. 3. Third laparotomy. Mature grade 0 glial implant. (Hematoxylin and eosin. Original magnification ×200.)

At the second operation 10 months later, multiple tissue fragments from the cul-de-sac measuring up to 10 cm in diameter were received. Extensive sectioning showed a fibrous, collagenous background, with numerous mature glial-neural nodules without evidence of immature elements (Fig. 2). The tissue contained some small cystic structures lined by cytologically bland, mature, ciliated and nonciliated columnar cells. The combination of mature glia and benign epithelial cysts was interpreted as mature teratoma. Multiple biopsies of smaller nodules from the surface of the cecum, descending colon, and bladder showed identical mature glial tissue, without immaturity. Specimens from the omentum, diaphragms, and pelvic lymph nodes were negative for malignant tumor.

The third laparotomy, performed 22 months after the first operation, revealed a corpus luteum cyst of the right ovary. Multiple biopsy specimens from the surface of the rectosigmoid colon, bladder, and small bowel showed mature glial implants, without immaturity or other teratomatous elements (Fig. 3).

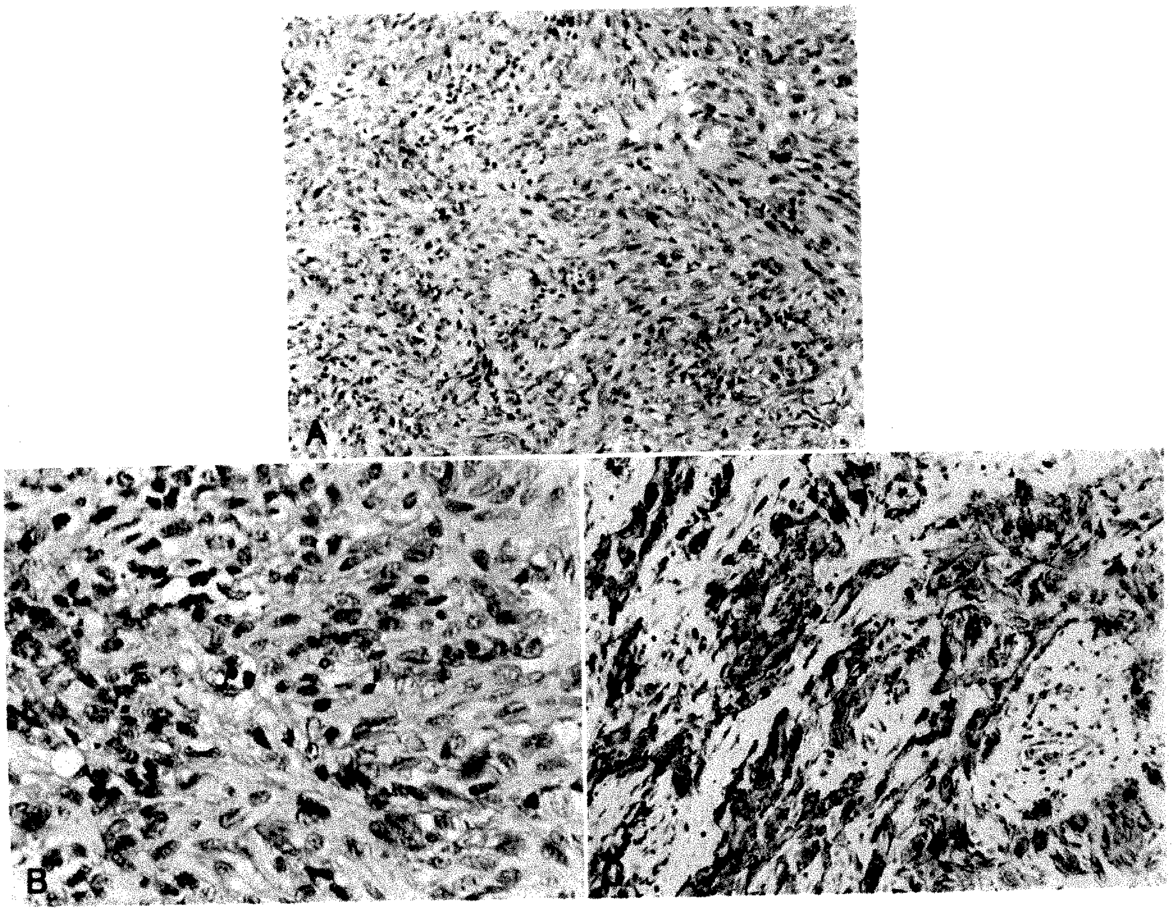

Fig. 4. Fourth laparotomy. **A,** Cellular, high-grade malignant glial tumor. (Hematoxylin and eosin. Original magnification ×200.) Compare with Figs. 2 and 3. **B,** Malignant glial tumor. (Hematoxylin and eosin. Original magnification ×510.) **C,** Tumor cells positive for glial fibrillary acid protein. (Original magnification ×200.)

The fourth laparotomy, performed 67 months after the original operation, showed a large anterior abdominal wall mass, as well as multiple nodules on the large and small bowel and in the area of the previous omentectomy site. The microscopic sections of these nodules revealed a highly cellular malignant tumor, with round and spindle-shaped cells exhibiting marked nuclear pleomorphism that infiltrated the anterior abdominal wall skeletal muscle (Fig. 4, *A* and *B*). The tumor did not form malignant mesenchymal structures or definite teratomatous foci, and there were no neuroepithelial rosettes, as seen in the original immature ovarian teratoma. The tumor cells were cytokeratin negative and were positive for both S-100 protein and glial fibrillary acid protein (Fig. 4, *C*). We interpreted this tumor as a malignant glial neoplasm, more analogous to a malignant glioma than to metastatic immature teratoma.

Review of literature

Gliomatosis peritonei is the implantation of mature glial tissue on the peritoneal surfaces, usually in association with solid ovarian teratomas. Proskauer[3] reported in 1946 the first series of 10 cases of this rare condition. In 1982 Truong et al.[4] reported two new cases and reviewed the world's literature, which at that time consisted of 30 cases. Since that time, several more cases have been reported, including a recent series of 13 patients reported by Harms et al.[5]

The prognosis of immature ovarian teratoma is closely associated with tumor grade.[6] The primary tumor and implants are graded according to the criteria of Thurlbeck and Scully,[7] which was later modified by Norris et al.[6] In the series of Norris et al. of 58 patients, 5-year survival rates for patients with grades 1, 2, and 3 were 82%, 63%, and 30%, respectively. However, in contrast to these survival figures, patients who have immature ovarian teratomas in association with mature glial implants appear to have a much improved prognosis.[1, 5] This latter statement is clearly dependent on two important factors: (1) Peritoneal surfaces and omentum must be thoroughly sampled histologically, including diaphragmatic surfaces; (2) all of the implants must be mature, i.e., without immature elements.

If these two conditions are met, the prognosis of the disease is excellent.

There are three cases in the literature that reportedly had adverse outcomes. Albites[8] reported a case in 1974 of a 9-year-old girl with a 19 cm ovarian teratoma described as mature, with grade 0 peritoneal glial implants. The report does not describe extensive peritoneal sampling. The patient was readmitted 14 weeks later with a large, left upper quadrant mass. The patient died 5 months after the initial operation. The rapid recurrence of disease and death of the patient suggest that areas of immature teratoma on the peritoneal surface were not sampled. Khoo et al.[9] in 1978 described a 17-year-old girl who presented with a 15 cm grade 2 immature ovarian teratoma, with grade 2 peritoneal glial implants; she died of disease 12 months after presentation. This case again fails to meet the two previously listed criteria because the glial implants were not completely mature. Nielsen et al.[10] reported four cases of gliomatosis peritonei in 1985. Their case 3 was a 29-year-old woman with a 25 cm, grade 3 immature teratoma, with grade 0 peritoneal implants of the omentum. However, diaphragmatic and peritoneal implants were present but not extensively sampled. One month later the patient underwent a second operation, and a 15 cm malignant teratoma was found. We interpret this as recurrent immature teratoma because of the rapid recurrence and inadequate sampling, rather than malignant transformation of the grade 0 glial implants.

Comment

The patient described in this article represents a unique case. After initial presentation with a grade 3 immature ovarian teratoma (the patient did not initially undergo staging), two subsequent laparotomies revealed mature peritoneal glial implants without areas of immature teratoma. In addition to extensive lymph node dissection and omentectomy, extensive peritoneal tissue sampling was performed during each of these laparotomies. A final laparotomy, performed >5 years after initial presentation, revealed a cytologically malignant glial proliferation. The glial nature of these malignant cells was confirmed by the expression of glial fibrillary acid protein. We interpret this case as an example of malignant transformation of benign peritoneal glial implants, which resulted in the eventual death of the patient.

In summary, gliomatosis peritonei is a rare condition, that generally imparts a favorable prognosis to patients with immature ovarian teratomas. Therapy should be directed by the grade and stage of the primary tumor and not by the glial implants, if they are extensively sampled and all are mature.[1, 4] If patients undergo extensive staging, peritoneal implants are well sampled, and histologic description shows the implants to be completely mature, a benign clinical course is to be expected. The current case appears to be a unique exception to the excellent prognosis of this condition and emphasizes the need for continued clinical evaluation and long-term follow-up, even in the face of mature peritoneal glial implants.

Discussion

DR. WILLIAM CRISP, Phoenix, Arizona. Gliomatosis peritonei is defined as metastatic implantation of neural glial tissue on peritoneal surfaces, usually in patients who have an immature ovarian teratoma. This condition is rarely found with mature teratomas, despite the fact that neural tissue may be found as a component in >30% of mature teratomas. Grossly, gliomatosis peritonei has the appearance of stage 3 ovarian carcinoma and is associated with an adherent capsule or a capsular defect in the parent teratoma in >90% of cases. It is important therefore to excise all ovarian teratomas intact. The potential occurrence of gliomatosis peritonei raises the question of whether the increasing incidence of laparoscopic ovarian cystectomy is desirable.

After an adequate sampling of the metastatic glial implants is taken for pathologic examination, all the implants should be removed. I think that this is best accomplished by using a Cavitron ultrasonic surgical aspirator (Cooper Biomedical Corp.). If the peritoneal implants are histologically mature, they are considered benign, provided that an adequate sampling of the ectopic neural tissues has been done to exclude the presence of germ cell elements and other types of neural tissue. Robboy and Scully[1] have published a classification with a scale from mature to immature that relates to the prognosis. The behavior of ectopic neural tissue as it ages is difficult to predict, as evidenced by the case under discussion.

Adjuvant therapy of malignant gliomatosis peritonei[2] with irradiation and chemotherapeutic regimens has been ineffective. However, there have been promising reports in the neurosurgical literature of immunologic therapy of ectopic malignant glial tissue.[3] Adoptive transfer of autogenous lymphokine-activated killer cells induced in vitro with recombinant interleukin-2 has been used in three patients with central nervous system malignant meningeal gliomatosis. This treatment was effective in reducing all central nervous system symptoms and in eliminating malignant cells from the cerebrospinal fluid. Follow-up on these patients has been for 3 years, and ectopic neural tissue is known to be a continuing threat that demands vigilant follow-up.

Dr. Shefren, what amount of ectopic glial tissue was left at the primary and other operations? Was immunotherapy considered?

Dr. Shefren (Closing). Immunotherapy was not considered in this patient, but it does seem to be something that might be considered for what has otherwise been unsuccessful treatment of this disease.

The use of potassium-titanyl-phosphate laser for laparoscopic removal of ovarian endometrioma

Richard P. Marrs, MD
Los Angeles, California

From January 1989 through January 1990, 31 patients thought to have ovarian endometrioma at ultrasonography were treated by operative laparoscopy and potassium-titanyl-phosphate laser. The endometriomas ranged from 2 to 9.2 cm in diameter by preoperative transvaginal ultrasonography. The operative procedure used was a three-puncture technique with a 600 μm fiber attached to a potassium-titanyl-phosphate laser. The power setting was 10 W with a continuous pulse. In all cases endometriomas were opened, drained, and irrigated, and the potassium-titanyl-phosphate laser was used to vaporize or remove the entire cyst lining. The ovarian edges were inverted with the laser at the end of the procedure. With one exception, there was no recurrence of endometrioma at 1, 3, and 6 months after the procedure, on the basis of transvaginal ultrasonography or laparoscopy. In one case, 4 months after the initial laparoscopic procedure, exploratory laparotomy was performed for resection of a large, recurrent endometrioma. The use of the potassium-titanyl-phosphate laser allows the laparoscopic surgeon an aggressive approach to ovarian endometriomas that in the past necessitated exploratory laparotomy. (AM J OBSTET GYNECOL 1991;164:1622-8.)

Key words: Potassium-titanyl-phosphate laser, endometrioma

Pelvic endometriosis is a commonly identified factor during the evaluation of the infertile woman. Controversy still remains as to therapeutic approach and outcome concerning the infertile state.[1-4] Normally endometriosis can be diagnosed only at the time of pelvic visualization by laparoscopy, culdoscopy, or exploratory laparotomy. However, the presence of ovarian involvement may be suspected on a clinical basis by visualization of cystic structures with transvaginal ovarian ultrasonographic scanning.[5]

With the advent of endoscopic laser technology, an aggressive, less invasive approach to pelvic endometriosis has become available. In the past the presence of ovarian endometrioma usually necessitated exploratory laparotomy and ovarian cystectomy or oophorectomy.[6] This report explores the use of an aggressive laparoscopic approach to ovarian endometriosis with laser ablation or resection.

Material and methods

Patient group. The study group was composed of 31 infertile women who were referred to our center from January 1989 through January 1990 for ovulation induction, gamete intrafallopian transfer, or in vitro fertilization and embryo transfer. The duration of infertility in these patients ranged from 18 to 68 months. The age range was 26 to 43 years, with a mean of 35.7 years. Before ovarian stimulation, all patients underwent transvaginal ovarian ultrasonographic scanning of the ovaries with ATL Ultramark 4 equipment and a 5 MHz transvaginal ultrasonographic probe (ATL, Bothell, Wash.). Visualized cystic-solid ovarian masses ranged from 2 to 9.2 cm in diameter. A presumptive diagnosis of ovarian endometrioma was made on the basis of ultrasonographic appearance (Fig. 1).

All patients were placed on a regimen of leuprolide acetate (Lupron, TAP, Chicago) for 6 weeks to 3 months before the laparoscopic procedure. All patients had complete infertility evaluations before initiation of medical suppression, including full male factor evaluation. Before surgical intervention, patients signed informed consents for laparoscopy, possible exploratory laparotomy, and possible oophorectomy.

Operative instruments. A potassium-titanyl-phosphate laser (KTP/532, Laserscope, Santa Clara) was used in all cases. The laser energy was delivered through a 600 μm core flexible quartz fiber. The usual energy level was 10 W with a continuous pulse mode. The fiber was passed through the operating channel of a 10 mm Wolf operating laparoscope (Richard Wolf Medical Instruments Corp., Rosemont, Ill.). Secondary instruments (5 mm) were placed in the pubic hairline in the right and left lateral margins under direct visualization, after transillumination of the potential puncture site. Grasping and suction/irrigation instruments were used through these 5 mm ports.

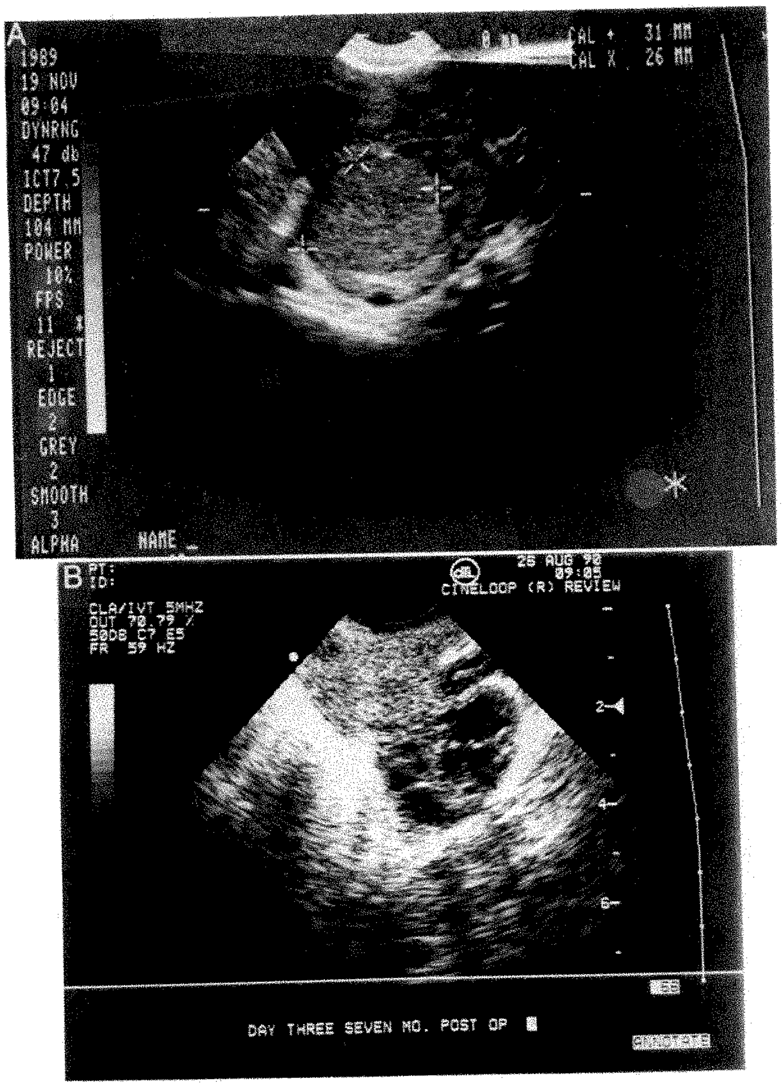

Fig. 1. A, Preoperative ultrasonographic scan of 3.1 × 2.6 cm left ovarian endometrioma. **B,** Transvaginal ultrasonographic scan of same patient. Normal left ovary on day 3 of cycle, 7 months after laparoscopic laser resection.

Operative procedure. Salpingolysis and ovariolysis were performed in all but two cases. These cases had a single endometrioma with no adhesions, ovarian fixation, or peritoneal implants of endometriosis. In the remaining 29 operative procedures, ovarian fixation was present. Before the cyst was opened, the structure was aspirated to ensure the diagnosis. Ovariolysis was then performed with the potassium-titanyl-phosphate laser to completely mobilize the ovary and endometrioma. The endometrioma was opened in a linear fashion over the area of marked protrusion from the ovarian surface, and the cyst was thoroughly irrigated and inspected for areas of excrescence. With operative scissors, a portion of the cyst wall was removed for pathologic evaluation (Fig. 2, *A*).

In cases where the endometrioma was ≤ 4 cm in diameter, the cyst wall was opened and the potassium-titanyl-phosphate laser was used to photocoagulate or vaporize the entire cyst lining. In larger endometriomas the cyst wall was dissected from the ovarian stroma and removed intact. Unipolar coagulation was used for hemostasis. Once the endometrioma was removed, the ovarian capsule was retracted by directing the laser to the undersurface of the cut edge of the ovary and effectively inverting the ovarian edge, thus decreasing the exposure of denuded ovarian surface (Fig. 2, *B*).

Results

Laparoscopy was performed after a presumptive diagnosis of ovarian endometrioma, on the basis of transvaginal ultrasonographic visualization in all 31 cases. Thirty of these patients had endometrioma and stage

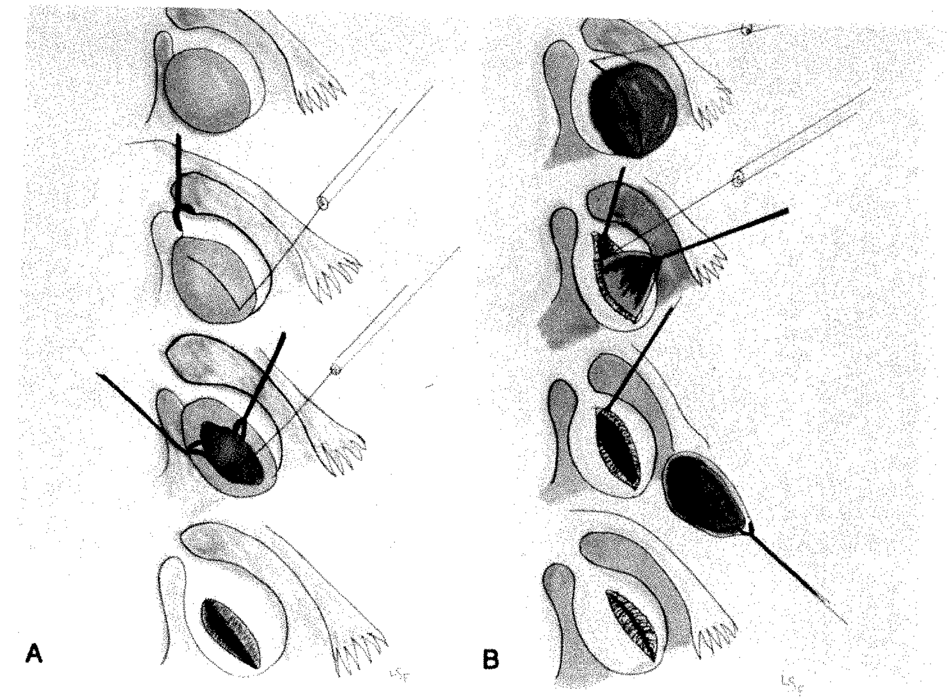

Fig. 2. A, Laparoscopic technique for laser ablation of endometrioma ≤4 cm in diameter. **B,** Laparoscopic laser cystectomy for endometrioma.

III or IV endometriosis (revised American Fertility Society classification); one patient had a 2 cm cystic teratoma (dermoid). All lesions (including the dermoid) were removed by operative laparoscopy and potassium-titanyl-phosphate laser. All procedures were performed by the author with the patient under general anesthesia in an outpatient surgical facility. Patients were discharged the day of operation, after an average recovery time of 4.3 hours. The surgical time ranged from 40 to 103 minutes, with an average of 52 minutes per case. The blood loss did not exceed 100 ml in any case and averaged 30 ml. All cases were completed laparoscopically, and there were no complications such as bowel, bladder, or vascular injury.

Time of follow-up ranged from 6 to 21 months. All 31 individuals have had follow-up transvaginal ultrasonographic examinations at 1, 3, and 6 months (Fig. 1, *B*). A recurrent endometrioma was observed in only one case; it was removed by exploratory laparotomy and ovarian cystectomy (Table I).

Twenty-three of the 31 patients have actively attempted pregnancy after the laser surgical procedure. Among these, seven pregnancies have occurred. In three patients, subsequent laparoscopy has been performed for gamete intrafallopian transfer, and no adhesions or evidence of endometrioma recurrence was visible.

Comment

This report demonstrates the usefulness of a laparoscopic approach for treatment of ovarian endometriomas. Moreover, it suggests that identification of ovarian endometriomas is enhanced with transvaginal ultrasonographic visualization of the ovaries in an infertile population.

The advantage of a laparoscopic approach to ovarian endometriomas is twofold. First, the patient avoids the physical and financial expense of hospitalization and exploratory abdominal surgery. Second, the risk of adhesion formation, theoretically and practically, should be decreased with a laparoscopic approach (Marrs RP. Unpublished data). In this study a subsequent laparotomy for endometrioma resection was required in only one of the cases. This patient (case 18) had a history of two previous laparotomies for treatment of stage IV endometriosis. At the time of laparoscopic resection, complete mobilization and access to the one remaining ovary could not be accomplished. In retrospect, a laparotomy approach would have been more suitable. However, in the remaining cases, where complete access and mobilization of the ovaries and cul-de-sac were accomplished, no recurrences have been seen. This compares favorably with the earlier report of Reich and McGlynn[7] using a laparoscopic approach.

The surgical approach settled on was initially somewhat arbitrary but in retrospect has been reliable. Endometriomas <4 cm are easily ablated with the fiber-delivered potassium-titanyl-phosphate laser. In lesions of this size, when an attempt at removing the cyst wall was made, bleeding from the adjacent ovarian tissue was usually encountered. Therefore the endometrioma was opened, drained, and irrigated, and the potassium-titanyl-phosphate fiber was used in a "paintbrush" fashion to completely photocoagulate all visible surfaces of the endometrioma lining. Although this technique can be used for endometriomas of any size, the time factor is more prohibitive in the larger lesions. It was easier to separate and remove the cyst wall in endometriomas >4 cm in diameter. In the case of the individual 9.3 cm endometrioma, the cyst wall was easily removed, and the remaining normal ovarian tissue was trimmed and left in place.

The pregnancy rate thus far in this small series of patients with a short follow-up is encouraging. Of the 23 patients attempting to conceive, seven patients have succeeded, with five either currently pregnant or already delivered. Even though only three patients have had laparoscopy after endometrioma resection, only minimal disease was visualized. This, combined with the number of patients conceiving, again suggests that a laparoscopic laser approach for this type of pelvic disease offers a very successful treatment modality.

These results compare favorably with a report by Kojima et al.[8] in which a neodymium:yttrium-aluminum-garnet laser was used for laparoscopic treatment of ovarian endometrioma.

In summary, a laparoscopic laser approach to ovarian endometrioma can be performed safely and efficiently. Surgeons experienced in operative laparoscopy and laser laparoscopy can use this approach without difficulty. The advantage to the patient is overwhelming, and patient acceptance is high. Thus the necessity for multiple laparotomies in patients with ovarian endometrioma is now avoidable.

Addendum

Since the preparation of this manuscript, three more patients have ongoing pregnancies and seven other patients have had second-look laparoscopy demonstrating no adhesions.

Discussion

Dr. Simon Henderson, San Francisco, California. Dr. Marrs has very elegantly presented us with another facet of advanced operative laparoscopy, namely, the destruction and removal of ovarian endometriomas with the potassium-titanyl-phosphate laser in women pretreated with leuprolide acetate. He has told us that seven pregnancies occurred among the 23 (30%) patients and that one of 31 (3%) had a large, recurrent endometrioma 4 months after the procedure, necessitating laparotomy and ovarian cystectomy. It will be interesting to hear from Dr. Marrs in another 2 to 3 years whether any of his other patients required further surgical treatment, since Hammond et al.[1] reported in 1976 that laparotomy and conservative surgery in women with severe endometriosis resulted in a 100% surgical recurrence rate, with the average time from the initial surgery to recurrence being 40 months. The original gold standard for pregnancy rates was set by Buttram[2] (1979) who performed laparotomy, ovarian cystectomy, and removal of as much endometriosis as possible in 47 patients with severe endometriosis. He achieved a 40% pregnancy rate with 15 months of follow-up.

Laparoscopic treatment of ovarian endometriosis has undergone a metamorphosis since Frangenheim[3] reported in 1978 that large endometriomas could be punctured and the contents aspirated, but 40% of these patients required subsequent surgical removal of endometrioma via laparotomy. Mettler and Semm[4] in 1983 first described laparoscopic ovarian cystectomy for endometriomas, involving removal of the capsule with scissors and closing the ovary with sutures. Reich and McGlynn[5] in 1986 reported laparoscopic excision of endometriomas using the unipolar knife electrode and leaving the ovary unsutured. Their patients were not pretreated with danazol or other drugs, and 10 of 21 (48%) achieved term pregnancies, with up to 8 years of follow-up. However, seven of 21 (33%) patients required further surgery for endometriosis. Nezhat et al.[6] in 1988 highlighted the need for excision of the cyst wall, since their recurrence rate was 50% in a group of patients treated with aspiration and irrigation of the endometrioma, compared with 8% for the group who had the cyst wall excised with carbon dioxide laser under video control. The pregnancy rates were 62.5% and 80%, respectively, for the two groups, both of which were treated postoperatively with danazol for 30 days. In June 1990 Kojima et al.[7] reported on 16 patients with infertility who had endometriomas removed with neodymium:yttrium-aluminum-garnet video laser laparoscopy without preoperative or postoperative treatment with danazol or gonadotropin-releasing hormone agonist. They used a cutting probe for opening the endometrioma and a lysing probe to dissect the cyst wall. Six (37.5%) patients achieved pregnancy and one (3%) patient underwent a subsequent laparotomy for removal of recurrent endometrioma. Four of nine patients who had second laparoscopies had mild periovarian adhesions. In both of these last-mentioned reports the ovary was left open.

On reviewing all my 113 cases of operative video laparoscopy between June 1989 and May 1990, I found 20 cases of ovarian endometriomas, 19 of which were treated with carbon dioxide laser vaporization, excision without closing the ovary, or pretreatment or posttreatment administration of gonadotropin-releasing hormone agonist or danazol. The large smoke production was not a problem with carbon dioxide insufflation flow rates of up to 6 L/min and use of the suction irrigation probe. The one patient not so treated had severe pelvic endometriosis with bilateral endometriomas 5 to 6 cm in diameter, which were completely adherent to the bowel and sidewall. These cysts were drained laparoscopically, and the patient was treated with 3 months of danazol before ovarian cystectomy and tubal microsurgery. In one of the 19 patients who had initially been treated laparoscopically for bilateral endometriomas of 5 cm each, a unilateral endometrioma subsequently redeveloped; she required danazol treatment for 2 months and subsequent laparotomy and ovarian cystectomy. Five of the 14 patients (36%) with ≥6 months of follow-up are pregnant.

I should also mention that Dr. Marrs' average operating time of 52 minutes was considerably lower than the operative times reported by Reich and McGlynn[5] and Kojima et al.[7], 80 and 90 minutes, respectively, and my own of 90 minutes.

The choice of laser is very individual, and Dr. Marrs has given his reasons for using the potassium-titanyl-phosphate laser. My reason for using the carbon dioxide laser is that it passes through the operating laparoscope almost along one's line of vision, often reducing the need for additional abdominal punctures and the need for another hand by one. The carbon dioxide laser has unsurpassed cutting and dissecting abilities; there is no chance of a fiber or probe breaking off. If you can see the structure to be treated, you can lase it, and if greater hemostasis is required, a needle electrode with pure coagulation or a blend of cutting and coagulation is always available through a secondary puncture.

In summary, Dr. Marrs' results compare very favorably with the results quoted by a variety of authors using electrosurgery or several different types of laser to remove endometriomas laparoscopically. I would not be surprised to see that his pregnancy and endometrioma recurrence rates are higher after longer follow-up.

My questions for Dr. Marrs are: (1) Did you use a video camera? (2) How many of your patients who conceived did so with the help of clomiphene, Pergonal, in vitro fertilization, gamete intrafallopian transfer, or other procedures? (3) Is it possible that vaginal ultrasonography will miss significant intraovarian endometriosis that might be capable of creating new endometriomas in the future?

Dr. James C. Caillouette, Pasadena, California. This procedure has many of the characteristics of an ovarian wedge biopsy. As you all know, the ovarian wedge biopsy for treatment of polycystic ovaries was used with great success for many years, until it lost favor because of the problem of adhesion formation. I am impressed, Dr. Marrs, that your procedures resulted in few adhesions, and therefore I have two questions: (1) Is there a place for the new product Interceed (Johnson & Johnson, Newark, N.J.) to lessen the likelihood of adhesions in this type of procedure? (2) Should we once again consider the possibility of ovarian wedge resection for the treatment of polycystic ovaries in those cases where there is no response to medical therapy?

Dr. Jack R. Lamey, Seattle, Washington. Medical therapy only, with danazol or gonadotropin-releasing hormone analogs, is an option for treatment of endometriomas measuring <4 cm. Dr. Marrs, what is the relative efficacy of medical therapy and laser surgery with regard to recurrence rates and pregnancy rates?

Dr. Philip G. Brooks, Los Angeles, California. Several studies[1, 2] have demonstrated hidden endometriosis, that is, microscopic endometriosis seen in random biopsy specimens of areas of peritoneum without visible lesions in patients who do have visible implants elsewhere. Dr. Marrs, would not medical treatment in conjunction with laparoscopic treatment improve pregnancy rates, because of the presence of endometriosis that is not treated with laser because it cannot be seen?

Dr. Louis A. Vontver, Seattle, Washington. Dr. Marrs, please comment on two questions. In one of the 40 cases in your series, the operative diagnosis was a dermoid, although the ultrasonographic examination was consistent with endometriosis. As the average age of your patients increases, the risk of an ovarian malignancy also increases. What happens if you open an ovarian lesion and find a carcinoma? (2) Should we have concern regarding possible carcinogens created by carbon particles left in an ovary, the capsule of which is also left open? Are you aware of any data on whether this procedure causes an increased risk for malignant transformation at a later date?

Dr. Marrs (Closing). Dr. Henderson, because of the nature of endometriosis, we are going to see recurrences among patients who do not conceive, and these will be at a rate that is unrelated to the treatment modality. Whether you do laparotomy with ovarian cystectomy, laparoscopic resection, or medical suppression, you are going to find recurrences at a later date. Even among those who do conceive, we have seen recurrences at a later date. The literature does not suggest that there is going to be a higher recurrence rate with laparoscopy.

The potassium-titanyl-phosphate laser has some advantages over the carbon dioxide laser. It is a more penetrating laser, and therefore you have more complete ablation of the cyst wall if you do not remove it. It has coagulating and vaporizing ability, and thus there is less need for electrosurgical coagulation.

Since all of these patients had stage III or IV endometriosis by the American Fertility Society revised classification, the largest amount of time in these procedures is spent in mobilizing the ovaries. Once this has been done, the ablation or resection of the endometrioma is relatively quick. We work hard to reduce the operating time because of our operating room schedule. First of all, the instruments and solutions are prepared and set out preoperatively so that the staff does not have to run to different rooms looking for them. Second, I do not work from the video screen but look through the laparoscope and use a beam-split video camera so that the assistant can view the procedure.

Dr. Caillouette, I have used Interceed in a number of other patients who had extensive laparoscopic lysis of pelvic adhesions or a laparotomy for myomectomy or aggressive adhesion lysis. It is easy to use and, if you can place it in over the ovarian lesion, it may further reduce the formation of adhesions.

I have not done a large number of second-look laparoscopies to date, but in those I have done I was surprised to see only a few, very filmy adhesions around the ovaries or anywhere else for that matter. I would not propose resurrecting wedge resection. There are very limited indications for surgical treatment of polycystic ovary syndrome and I would exhaust all other possibilities before using it. There are also some data in the literature[1] that laparoscopic laser drilling of the ovary in multiple sites offers some benefit to those patients with polycystic ovary syndrome who fail to respond adequately to ovulation-induction drugs.

Dr. Vontver, the risk of malignancy is always a concern. We examine these patients by ultrasonography and make a presumptive diagnosis at the time of laparoscopy. In this series no cases underwent laparotomy because of the appearance of the lesion. Even the dermoid was apparent when we aspirated the fluid contents. However, there will be patients with malignancy, and the question is whether you create problems by identifying the lesion at laparoscopy and then doing a laparotomy for treatment. I do not know. We are very cautious about doing these procedures in the older age group.

I do not know whether carbon particles left after laser may be potential teratogens in ovarian tissue. To be on the safe side, we do copious irrigation after any laser procedure. With the ovary, we irrigate with 3 to 5 L of lactated Ringer's solution.

Dr. Lamey suggested the use of medical suppression only for endometriomas ≤4 cm. We have done follow-up examinations of patients, who were found to have endometriomas at the time of later surgery, for up to 3 months while they received suppressive therapy and have seen absolutely no change in size or ultrasonographic consistency of the lesion in the ovary. I know of no data to support the contention that medical treatment will remove endometriomas in the ovary. It is a good preoperative treatment, but surgical removal is the only known therapy for elimination of endometriomas.

Dr. Brooks, I concur that systemic treatment before or after laparoscopy should enhance the pregnancy outcome, because it treats the microscopic foci of endometriosis that we know exist and cannot treat because we cannot see them. The existence of these microscopic lesions is one reason we have used combination therapy in cases with extensive pelvic endometriosis. An advantage of preoperative medical therapy is that the pelvic cavity is less vascularized and less edematous. I also think there is a reduction of postoperative adhesions. A disadvantage of preoperative treatment is that you may suppress endometriosis to the extent of making some lesions invisible and therefore they are not treated by laser at the time of the procedure.

Organ transplantation and pregnancy

A case report and review

E. Paul Kirk, MD
Portland, Oregon

The 1980s has been described as the "decade of transplantation" and organ transplantation as a "paradigm of medical progress." The considerable improvements in immunosuppression that have been made in the last few years have led to an increased repertoire of organ-to-organ combination transplants, more procedures, and markedly increased survival time for both grafts and recipients. Inevitably, there will be an increased number of women recipients who later undergo pregnancy. Although there is a wide experience with pregnancy after renal transplantation, there are as yet relatively few reports of pregnancy after other major organ transplants. A case is presented of a 22-year-old primiparous woman who elected to conceive and complete a pregnancy 2 years after cardiac transplantation because of cardiomyopathy. The pregnancy was complicated by a rejection episode early in the third trimester but eventually resulted in forceps delivery of a live male infant at 41 weeks' gestation. The pregnancy and organ transplantation literature is reviewed with special attention, illustrated by the case report, to the physiologic adaptation to pregnancy of the transplanted organ, the potential teratogenic effects of the immunosuppressive drugs used in pregnancy, and the contrasts between renal and other major organ transplants. (Am J Obstet Gynecol 1991;164:1629-34.)

Key words: Organ transplantation, pregnancy

In what was essentially an open letter[1] to bioethicists and philosophers in the January 1990 Hastings Center Report, Leonard Bailey, professor of surgery at Loma Linda University School of Medicine, made a plea for the development of the wisdom of predictive bioethics to replace the reactive bioethics that has surrounded the medical progress of the last two decades. In developing his argument, he described organ transplantation as a contemporary paradigm of medical progress, an idea generated by the desire to help individuals with critical problems, a goal that was initially ahead of its science, but one that has come of age in the last decade, with much improved results but with unresolved societal questions regarding the availability and distribution of resources.

Major organ transplantation is clearly here to stay. Although renal transplantation has been with us for the last two decades, we are now beginning to see young women whose health and reproductive function have been restored by other organ transplants and who are seeking preconception counseling and obstetric care.

This article will briefly describe one such case and then review the current information available to the patient and obstetrician facing the clinical situation with specific reference to renal, heart, and liver transplants.

Case report

A 21-year-old white woman, gravida 3, para 0, was referred for obstetric care at 8 weeks' gestation, 21½ months after orthoptic cardiac transplantation. She had a mitral valve replacement at age 18, followed by a progressive cardiomyopathy resulting in end-stage cardiac disease after 1 year. On referral she was taking 175 mg cyclosporine twice daily, 7.5 mg prednisone daily, 100 mg azathioprine (Imuran, Burroughs-Wellcome Co., Research Triangle Park, N.C.) daily, and 10 mg nifedipine at bedtime. Hematocrit was 34.3%, blood urea nitrogen 28 mg/dl, creatinine 1.1 mg/dl, and cyclosporine level 75 ng/dl. Blood pressure was within the normal range, and the nifedipine was discontinued early in pregnancy. The pregnancy was monitored in a routine manner, with serial ultrasonography demonstrating appropriate growth. Laboratory values were unchanged, apart from a fall in hematocrit to 28% at 30 weeks, and weekly nonstress tests and biophysical profiles showed normal results from 34 weeks' gestation.

Cardiac muscle biopsy at 8 weeks showed mild acute rejection. At 15 weeks there was no evidence of rejection, but mild acute rejection was again noted at 22 and 25 weeks, and moderate acute rejection at 30, 32, and 36 weeks. The rejection was treated by an increase in cyclosporine to 420 mg daily and a minipulse of prednisone. Maximum recorded levels of cyclosporine were

6/6/28686

at 127 ng/dl. At 40 weeks there was no evidence of rejection on cardiac biopsy. A mild bronchospasm developed in early pregnancy that the patient had not previously experienced. This persisted throughout much of the pregnancy and was treated with theophylline.

Labor was induced in the latent phase by artificial rupture of the membranes and oxytocin infusion at 41 weeks' gestation. Progress was normal to 6 cm dilation, but the active phase was then somewhat prolonged. After another 6 hours, labor became arrested with the vertex 5/5 engaged at the +3 station, directly occipitoposterior, with a persistent anterior lip of cervix. The patient had received an epidural anesthetic on entering the active phase of labor. A My-T-Vac vacuum extractor was applied to the fetal head, complete dilation was achieved, and Luikart Simpson forceps was applied, with delivery of a healthy male infant after light traction through three contractions. Infant weight was 2835 kg, and Apgar scores were 9 and 9. Arterial cord gases included pH 7.14, P_{CO_2} 46 mm Hg, P_{O_2} 20 mm Hg, bicarbonate 15 mEq/L, and base excess 15.3 mEq/L. Broad-spectrum antibiotics (vancomycin, gentamicin, and clindamycin) were given at rupture of the membranes and continued into the postpartum period. Obstetric intervention was decided on to limit the risks of infection potentially associated with cesarean section in labor and to limit the effects of prolonged maternal effort associated with a persistent posterior position of the fetal head. The infant, who was not breast-fed, made normal progress in the postpartum period and is now apparently normal, at age 1 year. The patient made normal progress in the immediate postpartum period. She was readmitted to the hospital after 1 month, with an episode of theophylline toxicity. She was discharged after 24 hours. The patient had a laparoscopic sterilization by Falope ring application 6 months post partum. She is now doing well with no signs of rejection.

This patient was not particularly assiduous in seeking preconception counseling, but others have been, and a systematic approach is helpful. Particular consideration should be given to the specific organ transplanted and the general and individual expectations for that transplant, the existence of comorbidity (sometimes the primary condition that led to the transplant), an understanding of the physiologic adaptation of the transplant to pregnancy, an appreciation of the teratogenic and other effects of the immunosuppressive drugs, an appreciation of the potential for organ rejection during pregnancy and how the signs of rejection may be distinguished from other pregnancy considerations, the need to individualize pregnancy management, and, as an amalgam of all the foregoing, the sense of how informed consent is or can be given in any pregnancy.

Transplantation expectations

Cardiac transplants. In the last decade there has been a rapid increase in the number of heart transplant operations performed, with approximately 2500 being reported to the registry of the International Society for Transplantation in 1988.[2] The mean age of patients undergoing transplantation is currently 43.8 years for heart recipients and 29.4 years for heart-lung recipients. Of these, 17% of heart recipients and 59% of heart-lung recipients are female. The 5-year actuarial survival for all orthoptic heart transplant patients was 73.9% and 81.9% for those receiving triple-drug therapy. At 10 years, the survival is 73.3%. By far the greatest mortality appears in the first year.

The major indications for cardiac transplant include coronary artery disease and cardiomyopathy, the latter being more likely to be the indication in young women and unlikely to be associated with significant comorbidity. However, it is important to recognize that 20% of patients will have some degree of allograft vasculopathy.

Hepatic transplants. Long-term survival data for liver transplantation are limited. The United Network of Organ Sharing reports 80% to 85% survival at 1 year and 70% to 75% at 3 to 5 years, with a slightly better survival in women.

Approximately 50% of the patients receiving a liver transplant do so because of chronic active hepatitis. Other indications include alcoholic cirrhosis, sclerosing cholangitis, hepatoma, primary biliary cirrhosis, and fulminant hepatic failure. These conditions are not usually associated with residual morbidity that has a deleterious effect on pregnancy, assuming restoration of normal liver function. Approximately one third of liver recipients are female, 75% of whom are likely to be within the reproductive age group, though most fall toward the upper end. Of 43 patients receiving transplants at Oregon Health Sciences University in the last 2 years, eight were considered to be of childbearing age.

Renal transplants. Evaluation of the circumstances for renal transplant patients differ from heart and liver transplants in two respects. It is possible, of course, for the graft to fail and the patient to survive and the 5-year graft survival varies considerably according to the origin of the graft.

Patient survival after renal transplant is 98% after 1 year, decreasing thereafter by 2% per year. For cadaver grafts survival is 85% for 1 year and 75% for 3 years, and for living related grafts it is 90% for 1 year and 85% for 3 years. In our program 62% of recipients have been male, and 38% female, with the mean age of female recipients being 43 years. While the survival data for renal transplantation are impressive, there remains a high rate of complications, even in those patients with long-term survival. In an article, "Life After Transplantation,"[3] describing the myriad of problems—emotional, financial, physical, and cultural—that transplant recipients experience, one patient states that "transplantation is more a syndrome than a disease because it is actually many diseases. You are trading one disease—the one you had before transplantation—for many others, but these others are treatable." In a study of 57 patients who survived with a functioning allograft for 10 years or longer in a single program in Minnesota[4] and who were studied for a mean of 2.2 years into their second decade, seven patients died, seven had a graft loss, and 40% of patients experienced complications from significant infections (hypertension, hyperlipidemia, liver disease, and musculoskeletal problems). Cataracts developed in one third, one fourth experienced rejection, and 16% had malignancy, vascular occlusive disease, or gastrointestinal disorders. The continuing existence of other conditions that are likely to have an adverse effect on pregnancy is commonplace in renal transplant patients. In our program 33% of patients had insulin-dependent diabetes mellitis, 30% had chronic glomerular nephritis, 10% had polycystic kidney disease, 27% had miscellaneous indications, including infection, obstruction, and congenital defects, as the primary indication for transplantation. The presence of diabetes and hypertension and the possibility of compromised renal function are all likely to be associated with poor pregnancy outcome.

Physiologic adaptation

Cardiac. With only a handful of case reports of pregnancy after cardiac transplantation, there is as yet no body of information describing any changes that occur in the transplanted heart under the influence of pregnancy. Cardiac output is increased in pregnancy by a combination of increase in heart rate and stroke volume caused by an increasing cardiac size. In our patient an increase in cardiac output from the denervated heart was achieved by increasing the heart rate, but cardiac size and contractility were essentially unchanged. A second patient is currently being studied, and the combined results will be reported later.

Renal. The renal adaptation in pregnancy appears to be influenced more by the preexisting graft function than by the fact that the kidney is a graft. When renal function is normal, the glomerular filtration rate increases in the usual way, as shown by the prospective study by Davison[5] of 10 pregnancies, with the greatest increments occurring in those patients whose graft functioned best before conception, regardless of donor source or sex and the transplant-to-pregnancy interval. Some reduction in glomerular filtration rate and increased proteinuria during the third trimester were common and usually transient.

Hepatic. Of the few cases reported of pregnancy after liver transplantation,[6, 7] no particular comments have been made regarding liver function other than a report that liver function "remained normal."

Immunosuppressive therapy

The comment previously made that major organ transplantation's time has come is due in large part to the better understanding of the science of immunology and the use of immunosuppressive drugs. There is now extensive experience with the use of corticosteroids and azathioprine in pregnancy. Corticosteroids have been associated with an increased incidence of cleft lip and palate in animals, yet this has not been seen in humans. The potentially serious effects of maternal hypertension and fetal adrenal insufficiency are probably dose related and are unlikely to be seen at daily doses of <15 mg prednisone. It is impossible to determine whether steroid use plays a role in individual cases of intrauterine growth retardation and premature rupture of the membranes, as has been suggested.

There is now 30 years of experience[8] with azathioprine, the nitroimidazole derivative of 6-mercaptopurine. It is activated by conversion in the liver. Small doses are readily transferred to the fetus, but reported anomalies appear randomly at a rate of about 3%. Uncertainty remains regarding long-term effects, particularly with reference to reproductive potential and risk of malignancy. Chromosomal abnormalities seen in one infant disappeared after 1 year. Leukopenia and thrombocytopenia may occur but are not seen when the leukocyte count is maintained at a normal level. Cyclosporine, a fungal peptide, was first introduced in 1978 and has significantly reduced rejection episodes in cadaver transplants. It crosses the placenta readily and is highly lipid soluble.

Animal studies with doses two to five times the therapeutic level have demonstrated an increased incidence of fetal and neonatal death, growth retardation, and diverse skeletal malformations. One hundred sixteen pregnancies have been reported to the manufacturer (Sandoz Pharmaceuticals, East Hanover, N.J.) with isolated cases of abnormality, none reported more than once, although intrauterine growth retardation was frequently observed.

Pregnancy outcome after renal transplant

Considerable experience[9, 10] has accumulated in the last two decades regarding pregnancy outcome in renal transplants. Initial individual case reports were followed by small cohorts from individual centers by literature review with aggregate reporting and questionnaire surveys. Unfortunately, this sequence has led to an inconsistency in the reporting, so that it is not possible to describe precise outcome figures. In summary, there has been a high therapeutic abortion rate of up to 30%, a high premature birth rate (<37 weeks) of

45% to 60%, a 30% incidence of preeclampsia, and a 20% incidence of intrauterine growth retardation. With the relatively small numbers and the method of reporting, the perinatal death rate is hard to pin down but appears to be of the order of 5%. Pregnancy outcome appears significantly improved if the pregnancy is delayed for at least 2 years after the transplant and if preconception renal function is normal.

One article from South Africa[11] reported 22 live births from 38 pregnancies with seven neonatal deaths. The more successful pregnancies were associated with the absence of warfarin, less immunosuppression, and compliance in taking medication.

Comment

It is now 32 years[12] since the first reported post–renal transplant pregnancy, and a considerable experience has accumulated. It is estimated that one of every 50 women of childbearing age with a functioning transplant will become pregnant. Pregnancies have also been reported after liver, pancreatic,[13] bone marrow,[14] heart-lung, and heart transplants,[15, 16] but these reports, including the case reported here, are single case reports and there is no accumulated experience as yet. The role of the obstetrician as a member of the transplant team has been discussed by Kossoy et al.[17] and presents somewhat of a dilemma. The improvement in survival after major organ transplantation is impressive, and many recipients are able to lead normal lives and resume their employment. It seems churlish to deny a young woman the opportunity of a pregnancy as part of the resumption of a normal life-style. On the other hand, these patients do not lead what for others would be a normal life and do not face a normal life expectancy.

In the ideal situation, the obstetrician will be able to consult with the patient and her family before she makes the decision to conceive. Discussion will include evaluation of the risks of pregnancy and the significance and problems of parenthood in this context. Although there have been individual case reports of maternal death associated with pregnancy after renal transplant, it appears that pregnancy itself carries relatively low immediate risk to the mother. The problems surrounding pregnancy appear to be related to the existence of other morbidity and the potential adverse effects of the immunosuppression rather than the failure of the transplanted organ to cope with the physiologic demands of pregnancy. The significant morbidity experienced by the fetus is largely associated with prematurity and growth, and with the continued improvement in outcome from the neonatal intensive care units, the morbidity is probably largely manageable. The patient then is presented with a choice. It has been calculated[18] that even with improved results there is a 50% chance that a parent with a renal transplant, male or female, will be dead before a child reaches 15 years of age.

These would appear to be poor odds, yet many women have chosen to go ahead and become parents as a result of the restoration of reproductive function and the establishment of normal life. One important question remains unresolved: Can we apply the data accumulated from the experience from renal transplants to the counseling provided to recipients of other organs? Is the generally poor outcome with renal transplants related to the function of the transplanted organ, the immunosuppression, or the coexistence of other disease, or might we expect better results with other organs?

As we enter a new decade, it is hoped that organizations such as the United Network of Organ Sharing may be encouraged to develop a registry of pregnancy outcome so that, along with the ethicists, we may be able to develop our skill as predictive rather than reactive providers.

Discussion

DR. HOWARD MCQUARRIE, Salt Lake City, Utah. Dr. Kirk's article includes an impressive case report of a post–heart transplantation pregnancy with favorable outcome for both the fetus, which was healthy, and the mother, who did not reject the transplanted heart.

At the University of Utah a heart transplantation program has been operational for 5½ years. Since our results may influence reproductive strategies after heart transplantation in other programs, I am pleased to present a summary and highlights of that program's results (personal communication, Dr. William Gay, Department of Surgery, University of Utah, Salt Lake City). From March 1, 1985, through Aug. 10, 1990, 329 heart transplants have been performed with a 96% 1-year survival rate and an actuarial 5-year survival estimate of 84%. Twelve men have fathered normal children after transplantation, but no women have borne children to date.

Three immunosuppressant drugs—corticosteroids, cyclosporine, and azathioprine—are consistently used in transplantation programs. They all cross the placenta, may affect the fetal immune systems, and, in addition, may be teratogenic. Corticosteroids have the most significant long-term effects in the heart recipient and possibly in the fetus. Some effects are infertility, abnormal bone growth, incomplete sexual maturity, and teratogenesis. Because of these risks, the goal of the transplantation program at the University of Utah is to discontinue steroids by 4 months after transplant. At present, nearly 70% of recipients are free of long-term steroid therapy by that time.

Pregnancy is a marvelously balanced, immunologically neutral state. With immunosuppressant therapy the relationship between the pregnant woman and her fetus is changed and both may have increased risks. Dr. Kirk, please comment on how the mother's immunosuppressant therapy may affect the fetus. Also, please comment on the counterpoint, the risk that lymphocytes or their metabolites that have been transferred from a nonsuppressed fetus may incite a rejection process in the mother.

DR. EMMET J. LAMB, Stanford, California. On Jan. 6, 1968, I arrived early in the morning for gynecologic surgery to find that my case had been bumped by Dr. Norman Shumway's first heart transplantation operation, the first in the United States. Since that time the transplantation team at Stanford has done well over 600 heart transplantations and close to 100 heart-lung or lung transplants (personal communication, Joan Miller, RN, Department of Cardiovascular Surgery, Stanford, Calif.). The cumulative 1 year survival over this period is 86% and the 5-year survival is 62%.

Because of their lower risk of coronary artery disease, young women are represented in the series in smaller numbers than young men, in a ratio of about 2 to 3. I do not know the number who are in the reproductive age group. The transplantation team discourages women from conceiving for the two reasons that Dr. Kirk discussed, the iatrogenic diseases common to any group of transplantation patients and concern about the ability of a denervated heart to compensate for the physiologic changes in pregnancy. Only two of these women became pregnant. One conceived within 2 years after heart transplantation because of peripartum cardiomyopathy; her pregnancy and delivery were uncomplicated. The baby, now 15 months old, and the mother are doing just fine. The other patient, who had transplantation because of a tumor of the heart, also had an uneventful pregnancy and delivery. The baby did well, but the mother died, about 6 months after her delivery, of problems related to the transplantation. This case has been reported.[1,2]

DR. THOMAS G. MOYERS, San Diego, California. About 2 years ago I had the opportunity to care for a 20-year-old woman with cardiomyopathy who, having undergone cardiac transplantation at Sharp Memorial Hospital in San Diego, had an uncomplicated pregnancy about 2 years later. She had a low-forceps delivery of a near-term fetus in good condition; she did well post partum. In the last year a rejection syndrome has developed and she is being considered for a second transplantation operation. Dr. Kirk, how many pregnancies have been reported in patients who have undergone cardiac transplantation? In my review of the literature I have not found very much on the subject.

DR. KIRK (Closing). Dr. McQuarrie, I do not have any specific recommendation for a strategy to reduce the risk of rejection. From the renal transplantation experience, it does not seem that delivery itself increases the risk of rejection in any obvious way. The 9% rate quoted by Davison[1] in a general review includes a whole variety of sources of information. Immunologists tell me that bromocriptine is an immunosuppressant and that the suppression of lactation is appropriate because it is not recommended that patients breast-feed because of the effects of the drugs on the fetus.

Dr. Lamb, I appreciate your historic vignette. One of the messages that I wanted to get across was that, even though the transplantation teams may be advising their patients not to conceive, patients will conceive. We have to give them as much up-to-date information as we can. The cases you and Dr. Moyers cite again highlight two issues: (1) the need to get a central registry of pregnancies after transplantation and (2) the ethical issues we face all of the time. The focus often is on the 9 months of gestation, whereas the issue really is all that becoming a parent means.

Transabdominal cervicoisthmic cerclage: A reappraisal 25 years after its introduction

Miles J. Novy, MD
Portland and Beaverton, Oregon

Most cerclage operations for cervical insufficiency are performed transvaginally. The transabdominal route is beneficial in treating patients with cervices that are either extremely short, congenitally deformed, deeply lacerated, or markedly scarred because of previously failed transvaginal cerclage procedures. The average gestational age at surgery was 11.5 weeks and the operation was performed after early ultrasonographic verification of fetal viability. Patients with advanced cervical effacement or dilatation in the second trimester were excluded. A 5 mm wide Mersilene band was applied in an avascular space above the junction of the cervix and the uterine isthmus without dissection or tunneling among broad ligament vessels. This simplified surgical approach resulted in little operative blood loss (mean, 75 ml; range, 50 to 200 ml). After transabdominal cervicoisthmic cerclage, 21 pregnancies in 20 patients resulted in 18 term births, one premature birth with favorable outcome, and two early fetal deaths (90% salvage rate). A review of the world literature indicated 130 pregnancies with transabdominal cervicoisthmic cerclage during pregnancy and a cumulative success rate of 89%. Preconceptional transabdominal cervicoisthmic cerclage was reported in 30 pregnancies with an overall fetal survival rate of 81%. A survey of specialists in maternal-fetal medicine indicated an increasing interest and familiarity with transabdominal cervicoisthmic cerclage since its introduction more than two decades ago although this procedure is still not widely applied in obstetric practice. (AM J OBSTET GYNECOL 1991;164:1635-42.)

Key words: Cervical defects, incompetent cervix, transabdominal cerclage

Most cerclage operations for cervical insufficiency are performed transvaginally. The transabdominal approach to cerclage placement above the cervix and around the uterine isthmus was originally described by Benson and Durfee[1] in 1965 at the Oregon Health Sciences University. The transabdominal route is beneficial in the treatment of patients with cervices that are either extremely short, congenitally deformed, deeply lacerated, or markedly scarred because of previously failed transvaginal cerclage procedures. The experience with this operation at the same hospital was expanded and updated in 1982.[2]

Since the introduction of transabdominal cervicoisthmic cerclage more than 25 years ago, modifications have been made in patient-selection criteria, surgical technique, timing of the operation, and preoperative and postoperative patient management. In recent years, several reports[3-5] from other centers on transabdominal cerclage techniques have appeared in the literature with uniformly favorable results and few complications reported. In an effort to appraise the significance of these modifications, our experience with transabdominal cervicoisthmic cerclage since 1982 is described. We also conducted a survey of specialists in maternal-fetal medicine to assess their familiarity with transabdominal cerclage techniques. Although transabdominal cervicoisthmic cerclage is still not widely used in obstetric practice, our survey suggests there is an increasing interest and familiarity with this procedure. The place for transabdominal cervicoisthmic cerclage in the management of recurrent second-trimester pregnancy loss and preterm delivery is discussed in the context of our current understanding of the pathophysiology of preterm labor and cervical incompetence.

Patients and methods

Twenty-two patients were selected for transabdominal cervicoisthmic cerclage and 20 patients were followed up through 21 pregnancies in an 8-year period from 1982 to 1990. With the exception of one patient who had transabdominal cervicoisthmic cerclage after extensive conization and near amputation of the cervix, all other patients had prior pregnancy losses in the second trimester or had experienced premature delivery (before 35 weeks' gestation).

The procedure was performed between 10 and 16

Table I. Clinical indications for transabdominal cervicoisthmic cerclage*

Condition	No. of patients
Marked scarring after failed transvaginal cerclage	18
Abnormally short or deformed cervix	
Diethylstilbestrol exposure	9
Müllerian anomaly	3
Extensive conization	4
Deep forniceal lacerations	5

*Several patients had more than one condition.

weeks' gestation (mean age, 12 weeks; median age, 11.5 weeks) after determination of fetal viability by ultrasonography in 20 patients and before conception in two patients. The patients varied in age from 27 to 40 years. All were multigravid women with a mean gravidity of 5 at the time of the operation. Preoperative patient evaluation included cervical and urine cultures for aerobic and facultative bacteria, *Chlamydia*, and genital mycoplasma organisms. Eight patients received erythromycin, 1 gm orally daily for a minimum of 10 days before surgery for positive cervical cultures for group B streptococci, *Mycoplasma* organisms, or empirically.

Eighteen patients had at least one previously failed transvaginal cerclage; eight patients had two failed MacDonald or Shirodkar procedures before transabdominal cervicoisthmic cerclage. The clinical selection criteria for transabdominal cervicoisthmic cerclage are listed in Table I. Several patients had more than one indication. All patients had abnormally short, markedly scarred, or deeply lacerated cervices. Nine patients gave a history of exposure to diethylstilbestrol in utero and all demonstrated short cervices and previously failed transvaginal cerclage procedures. Histories of predisposing or contributory factors such as obstetric or surgical trauma to the cervix were elicited from nine patients. Four patients had extensive cervical lacerations after traumatic or precipitous delivery or a uterine rupture. Four patients had extensive conization of the cervix because of cervical intraepithelial neoplasia and two patients had virtual amputation of the cervix after conization had been complicated by bleeding. Two patients had term deliveries before an extensive cervical laceration or wide conization, which in turn were followed by second-trimester fetal death. Three patients had deformed cervices in association with Müllerian anomalies. One patient had unicornuate uterus, one had a bicornuate uterus with rudimentary horn and double cervix, and another patient demonstrated vaginal agenesis and partial cervical atresia that had been treated by a modified McIndoe procedure. Transabdominal cervicoisthmic cerclage was placed as an interval procedure before conception in two patients, in one case at the patient's request and in the other case because the lower uterine segment was severely scarred from a previous uterine rupture.

Surgical procedures. Fourteen procedures were completed after induction of general anesthesia and seven after induction of regional anesthesia. Twenty operations were performed during pregnancy and two before conception. The peritoneal cavity was entered by a Pfannenstiel incision in 14 patients and by midline vertical abdominal incision in eight patients with a previous scar with known pelvic adhesions, or when difficult surgical exposure was anticipated.

Between 1982 and 1985, transabdominal cervicoisthmic cerclage was performed as previously described[2] in nine patients (group 1). After dividing the peritoneal reflection and advancing the bladder, the space between the ascending and descending branches of the uterine arteries was identified lateral to the uterine isthmus and a tunnel was developed by blunt dissection. After tenting the posterior leaf of the broad ligament with right-angle forceps, it was incised with Metzenbaum scissors and a 15 cm segment of Mersilene ribbon (0.5 cm wide, Mersilene 5, RS21, Ethicon, Inc.) without needles was passed under direct vision. An identical procedure was carried out on the opposite side. The Mersilene band was secured anteriorly with a triple square knot and the cut ends were fixed to the band with nonabsorbable sutures.

Our current and preferred technique was adopted after 1985 and was used in the other 13 patients (group 2). It is a modification of Mahran's technique[6] but with several important differences. After the lower uterine segment is exposed, the uterine vessels are located by palpation between the thumb and the forefinger and are drawn laterally away from the uterine isthmus. Preoperative planning and coordination between the surgeon and the assistants is essential to provide maximum exposure and to avoid injury to the dilated blood vessels. Elevation of the uterus out of the pelvis by the assistant is a critical step because it allows visualization of the uterine vessels, the isthmus, and the uterosacral ligaments. If the surgeon is right-handed, the 5 mm Mersilene band with swaged needle (RS21 with blunt tip) is passed in a posterior direction (on the patient's right side) through an avascular space between the retracted vessels and the uterine isthmus without penetrating the myometrium. The suture is passed above the uterosacral ligaments. The same procedure is performed on the opposite side but the needle enters from behind the uterus in an anterior direction. The band should lie flat and snugly and the knot is tied anteriorly with firm compression of the intervening tissue. Handheld retractors are preferable to self-retained retractors because they provide better exposure and more room to maneuver the uterus.

After the operation, the patient is monitored for blood loss and fetal viability. Uterine irritability is rare unless the cervix is effaced or dilated.[7] Prophylactic hormones, tocolytic agents, or antibiotics are not routinely administered after the operation. All patients were discharged within 4 to 7 days after transabdominal cervicoisthmic cerclage and the condition of the cervix was assessed by palpation at weekly or biweekly intervals. Cervical length and status were further assessed by transabdominal or transvaginal ultrasonography at periodic intervals.

Results

All patients have been followed up to the time of this writing. Of the 22 patients, four have elected to have a tubal sterilization procedure, two have had a hysterectomy, and 16 remain voluntarily fertile.

Fetal survival. The obstetric outcomes of 21 pregnancies in 20 patients who had transabdominal cervicoisthmic cerclage during pregnancy are tabulated in Table II and compared with the results in the same patients before cerclage. The two patients who had transabdominal cervicoisthmic cerclage in the nonpregnant state had not conceived after 6 to 12 months.

The overall fetal survival rate in patients after transabdominal cervicoisthmic cerclage was 90%; that before cerclage was 20% ($p < 0.01$). Of the 20 patients, one had two successful pregnancies and repeat cesarean section deliveries after the transabdominal cerclage.

The effect of transabdominal cervicoisthmic cerclage on the distribution of births by gestational age is shown in Table III. Seventy percent of the pregnancies before cerclage ended in late abortion. Five percent of the postcerclage pregnancies also did so. Likewise, 18% of the precerclage births but only 5% of the postcerclage births were premature (at ≤35 weeks' gestation). Ninety percent of the deliveries after transabdominal cervicoisthmic cerclage but only 12% of those before transabdominal cervicoisthmic cerclage resulted in live births at term. Two patients had term deliveries before an extensive cervical laceration or wide conization that led to subsequent second-trimester fetal death. Successful term deliveries were once again achieved after transabdominal cervicoisthmic cerclage in these two patients. The differences in the distribution of late abortions, premature deliveries, and term deliveries were highly significant statistically (χ^2, $p < 0.001$). All infants were delivered by cesarean section. A transverse incision was made in the lower uterine segment but the band was not disturbed.

Complications. In this series of 22 patients, 20 experienced no intraoperative or postoperative complications (i.e., no hemorrhage, sepsis, fever, premature rupture of the membranes, or premature labor). The majority of patients received prophylactic antibiotics in the operating room. In two patients, fetal death in utero occurred after transabdominal cervicoisthmic cerclage at 13 and 14 weeks' gestation, respectively. In one patient, transabdominal cervicoisthmic cerclage was placed uneventfully at 11 weeks' gestation after preoperative ultrasonography had shown a vanishing twin syndrome. Fetal heart tones disappeared without apparent cause at 13 weeks' gestation and the products of conception were evacuated without difficulty with the band in place. Chromosomal studies on the products of conception showed no abnormalities.

In the other patient, laceration of a uterine vein occurred during the blunt dissection and tunneling among broad ligament vessels. This led to an estimated blood loss of 450 ml. Hemostasis was achieved by the application of clips and by suture ligature. Fetal heart tones were lost on the sixth postoperative day, accompanied by vaginal bleeding. The fetus and products of conception were removed by cervical dilatation and curettage without removing the Mersilene band. Two days later, acute pelvic thrombophlebitis developed that required heparin and antibiotic therapy. The subsequent recovery was uneventful.

The average estimated operative blood loss differed significantly between patients who had placement of the cerclage by tunneling between uterine vessels

Table II. Obstetric outcome in 20 patients before and after transabdominal cervicoisthmic cerclage*

	Before cerclage	*After cerclage*

TCIC, Transabdominal cervicoisthmic cerclage.

(group 1) and those in whom uterine vessels were retracted manually (group 2). The latter procedure was adopted after 1985 and resulted in substantially less blood loss (Table IV).

Late prenatal complications after transabdominal cervicoisthmic cerclage consisted of premature labor in three patients (an incidence of about 14%) who responded to the administration of tocolytic agents. One patient experienced placenta accreta at 39 weeks' gestation, resulting in hemorrhage, shock, coagulopathy, and cesarean hysterectomy.

Questionnaire. We sent questionnaires to 435 members of the Society of Perinatal Obstetricians and 248 were returned (57%) (Table V). Eighty-six of the respondents (35%) stated they had personal experience with transabdominal cerclage and had performed between 1 and 25 procedures. Only ten obstetricians had performed more than 10 such procedures. Ninety-six percent of the respondents were familiar with the operation and 90% stated that transabdominal cerclage had a role albeit limited in comtemporary obstetric practice. A total of 404 transabdominal cerclage procedures were tabulated at the time of this writing, which is approximately three times the number reported in the world literature. Most (61%) were performed in the early phase of the second trimester of pregnancy and only 11% were done before pregnancy. Seventy-five percent of pregnancies resulted in term births and there was an overall uncorrected fetal survival rate of 87%.

Comment

Injuries to the cervix during childbirth or after extensive conization are major causes of traumatic cervical incompetence and result in a high rate of second-trimester abortion and premature delivery.[1, 8] In our series, cervical incompetence was attributed to surgical trauma (extensive cervical conization) in four patients and to deep forniceal lacerations in five others. In two patients, the cervix and lower uterine segment were lacerated and deformed as a result of a previous uterine rupture or extension of a transverse incision at cesarean section. In nine patients, the cervix was congenitally short (<1 cm or flush with the vagina) in association with diethylstilbestrol exposure in utero.

Cervical insufficiency may coexist with müllerian anomalies. One of our patients had a unicornuate uterus, another had a bicornuate uterus with rudimentary horn and double cervix, and a third patient had vaginal agenesis with cervical atresia. There is increasing evidence that cervical cerclage improves obstetric outcome in pregnancies complicated by uterine malformations,[9] although most gynecologists prefer a septum resection or metroplasty for the uncomplicated septate or bicornuate uterus.[10] Cerclage may be the only option for the patient who is delivered of an infant prematurely in association with the unicornuate uterus. We report a successful pregnancy after transabdominal isthmic cerclage in a patient with vaginal agenesis and cervical atresia treated by a modified McIndoe procedure.

The primary clinical considerations in choosing a transabdominal cerclage rather than a transvaginal procedure were marked scarring of the cervix and previously failed transvaginal cerclage procedures in 18 patients (82%) (Table I). In contrast to a previous report,[2] we did not perform emergency transabdominal cervicoisthmic cerclage for the patient with advanced cervical effacement or dilatation in the second trimester. Others,[3, 5] have reported a high incidence of premature rupture of the membranes under these conditions. Also, our recent success in the management of patients with a previable fetus and bulging membranes in the absence of symptomatic contractions would suggest that a combination of transvaginal Shirodkar cerclage, broad-spectrum antibiotic therapy, tocolysis, and inhibition of prostaglandin synthesis is preferable to transabdominal cervicoisthmic cerclage.[11]

TCIC, Transabdominal cervicoisthmic cerclage.

Fetal salvage rate after transabdominal cervicoisthmic cerclage in the series reported here was 90%. The precerclage rate for the same group of patients was 20% ($p < 0.01$). The cumulative results in the world literature of transabdominal cervicoisthmic cerclage performed during pregnancy are shown in Table VI. Since the original report by Benson and Durfee in 1965, there have been eight reports from other centers including this series. A total of 130 pregnancies have been followed up in 111 patients with an average fetal salvage rate of 89%. A smaller number of patients has been followed up after transabdominal cerclage performed before conception. Table VII indicates that a similar fetal salvage rate of 81% was achieved in 30 pregnancies. The consistent success of the transabdominal cerclage over more than two decades and in many different centers in this country and abroad is impressive. It surpasses the overall success rates reported for transvaginal treatments of the incompetent cervical os syndrome.[12] The success rate of transabdominal cervicoisthmic cerclage is especially noteworthy in view of the severe obstetric histories and the failures of transvaginal cerclage procedures in these patients. The superior results with transabdominal cervicoisthmic cerclage in contrast to transvaginal procedures may be explained in part by the specific criteria for cervical insufficiency in this selected group of patients and the higher anatomic placement of the cerclage.

The etiologic factors involved with the incompetent cervical os syndrome are commonly attributed to acquired causes (usually traumatic), congenital factors (e.g., müllerian malformations, or diethylstilbestrol exposure in utero), or functional causes (endocrine factors or infection). Clearly patients who have transabdominal cervicoisthmic cerclage are selected on the basis of anatomic or acquired cervical defects and thus represent a pure subpopulation of patients in comparison with the heterogeneous group that receives transvaginal cerclages. Even so, a substantial number of patients report a history of premature labor, premature rupture of the membranes, and chorioamnionitis in prior pregnancies but infrequently after transabdominal cervicoisthmic cerclage. There is increasing evidence that cervical or vaginal microflora, or the inflammatory reactions they produce, release factors (e.g., proteases, collagenases, prostaglandins, and lymphokines) that initiate or predispose the patient to uterine contractions, cervical ripening, and rupture of the membranes.[13, 14] Although speculative, the possibility exists that anatomic defects in the cervix predispose the patient to ascending lower genital tract infection and that in some way transabdominal cerclage procedures

Table VIII. Complications associated with transabdominal cerclage

Complication	*Incidence*	*References*
Excessive blood loss	Occasional	1,2,3,5

Persistent pain	Rare	6,18
Suture migration	Rare	2,5

bolster maternal host defenses to ascending infection by restoring the integrity of the cervical barrier during pregnancy.

Despite the efficacy of transabdominal cervicoisthmic cerclage in a selected group of patients, some researchers believe it has several disadvantages (i.e., the need for two intraabdominal procedures, surgical intervention in a highly vascular area, and a moderate complication rate).[12] The need for two abdominal operations during pregnancy cannot be denied but we have experienced few major operative complications and little maternal morbidity with transabdominal cervicoisthmic cerclage. Pelvic thrombophlebitis developed in one patient but there were no cases of maternal infection, premature rupture of the membranes, or chorioamnionitis in this series. Preterm labor occurred in three patients (14%) during the third trimester and was managed successfully with tocolytic agents. Fetal death, intrauterine growth retardation, suture migration, premature rupture of membranes, placental abruption, and excessive blood loss have been reported in the literature but they occur infrequently (Table VIII).[3-5]

In an attempt to avoid additional surgery during pregnancy and to circumvent operative blood loss, some researchers have recommended that transabdominal cervicoisthmic cerclage be performed as an interval procedure in the nonpregnant state. There is still insufficient experience with preconceptional cerclage to conclude that it is superior or even equivalent to operation during pregnancy. Moreover, several potential disadvantages to the performance of cerclage before conception have been reported. It may increase the difficulty of spontaneous abortions or contribute to dysmenorrhea or infertility.[15, 16] We prefer postconceptional transabdominal cervicoisthmic cerclage application because fetal viability can be confirmed and the tension applied to the Mersilene band is more accurately judged during pregnancy. A modification in our surgical technique has led to a significant reduction in operative blood loss and has virtually eliminated serious bleeding complications during surgery. The use of ultrasonography to determine fetal viability at 9 to 10 weeks' gestation has in turn allowed surgical intervention earlier in the first trimester of pregnancy. Earlier timing of the operation (at approximately 11 weeks' gestation) facilitates the surgery and reduces intraoperative complications.

In the 25 years since its introduction, there has been progressive worldwide use of transabdominal cervicoisthmic cerclage although it remains a specialized procedure. The results of our survey of perinatal obstetricians in the United States indicates that about one third have performed the procedure in their own practices. Nevertheless, a broad consensus was obtained that transabdominal cervicoisthmic cerclage is an established procedure that is tailored to a select group of patients with anatomic defects of the cervix and failed transvaginal cerclage. Because transabdominal cervicoisthmic cerclage is recognized as an effective and safe operation, it is unlikely that a prospective trial will ever be mounted. There is even serious concern that such a trial would be ethical. Moreover, a sufficient number of women have been described in the world literature who had normal term deliveries but after a distinct traumatic event (e.g., extensive conization) experienced repeated fetal death. The pattern of pregnancy wastage was then restored to normal by transabdominal cervicoisthmic cerclage. This sequence of events is analogous to the therapeutic response after other curative surgical procedures and is highly unlikely to be a chance phenomenon.

I thank VaLera Washburn and Patsy Kimzey for their expert assistance in the collection of data.

Discussion

DR. LYMAN RUST, Hanford, California. Dr. Novy has just presented his second article before this society describing his experiences with transabdominal cervicoisthmic cerclage. I reviewed this article with a great-deal of curiosity and interest because I have had no personal experience with this procedure. And, indeed, I have never been able to determine the indications for the transabdominal approach when the transvaginal procedures have served so well.

Dr. Novy discusses a survey of perinatologists of whom only 35% of the respondents had had personal experience with transabdominal cervicoisthmic cerclage. I would venture to say if a similar survey were taken of obstetricians who do not label themselves as perinatologists, this figure would be considerably lower. There are several important reasons for the lack of enthusiasm for this approach. First, most obstetricians have had excellent results with the classic transvaginal procedures developed by Shirodkar and MacDonald. Second, the transabdominal cervicoisthmic cerclage procedure has much greater morbidity, requires a second laparotomy for cesarean section, and is thus much more expensive. And third, the indications for transabdominal cervicoisthmic cerclage are strictly limited.

It is the latter point, the indications for transabdominal cervicoisthmic cerclage, that is the most important contribution of this article. Dr. Novy has selected his patients very carefully with well-defined criteria. However, with the obvious drawbacks of this procedure, these criteria need to be carefully scrutinized. As reported in the article, all 22 patients in this series had well-defined cervical deformity and 21 had previous pregnancy losses in the second trimester or premature delivery before 35 weeks' gestation. Eighteen of the 22 had a previous unsuccessful attempt at transvaginal cerclage and eight patients had two previous failures. That sounds like very strict criteria. However, I would emphasize that failure of a transvaginal cerclage per se is not necessarily an indication for the abdominal approach. Other causes of failure such as the indication for the initial cerclage, ruptured membranes, or bleeding should be considered and ruled out. Occasionally a cerclage stitch will tear out because of improper placement or because of the type of suture used. A No. 1 or No. 2 suture might cut through the cervix where a wide band (5 mm) Mersiline suture might not.

Also, patients with a short, scarred or deformed cervix can and have been successfully treated with transvaginal cerclage. A technique described by Jesse Rust with the use of a curved Allis clamp to grasp and gather the side of the cervix plus the gentle insertion of the index finger into the cervical canal to identify the internal os, allows for the safe placement of a deep stitch at the level of the internal os in most instances.

Therefore I would agree with Dr. Novy that the indications for transabdominal cervicoisthmic cerclage should be strictly limited to those patients who have a marked cervical deformity and who have failed a previously well-placed transvaginal cerclage.

Indications for use of transabdominal cervicoisthmic cerclage for patients with müllerian anomalies and women exposed to diethylstilbestrol still need verification. It is not clear from this article whether the three patients in this category had pregnancy losses consistant with cervical incompetance and whether they benefited from transabdominal cervicoisthmic cerclage.

Dr. Novy is to be congratulated on his perseverance with this procedure. He has developed modifications in surgical technique to lessen the risk of blood loss. However, performance of transabdominal cervicoisthmic cerclage in the first trimester needs to be questioned. Although ultrasonography allows early detection of fetal heart rate, two of his patients suffered loss of viability soon after surgery was performed. Maybe these losses resulted from the surgery or possibly they were doomed regardless. Most obstetricians believe that elective surgery is better performed in the second trimester after the pregnancy is well established and the uterus is more quiescent.

In closing, Dr. Novy is to be commended for his continued interest in and modifications of transabdominal cervicoisthmic cerclage and for clarification of the strict indications for this procedure. His results speak for themselves: transabdominal cervicoisthmic cerclage does work.

I have these questions for Dr. Novy:

1. Why were prophylactic antibiotics used? Do you have any controlled studies that show they are advantageous?
2. Did the patients with müllarian deformities have previous pregnancy losses consistant with incompetent cervix or were they done empericaly?

3. Were chromosomal studies done on the two fetuses that died after transabdominal cervicoisthmic cerclage.

Dr. Novy (Closing). Failure of a previous transvaginal cerclage should not be the sole indication for a transabdominal procedure. On several occasions patients have been referred to me for a transabdominal cerclage, but on examination I found that a transvaginal Shirodkar cerclage could be applied and it was done successfully with a good outcome. The decision to apply a transabdominal cerclage should be made on the basis of the obstetric history, the details of previous attempts at transvaginal procedures, and the current anatomic state of the cervix. A significant deformity, a laceration, extreme shortening, or severe scarring may make the transvaginal approach difficult.

Concern about operating in the first trimester of pregnancy is less today than it was before ultrasonography. We have ample evidence from studies relating to chorionic villus biopsy[1] that an ultrasonographic diagnosis of fetal viability at eight weeks' gestation is associated with a subsequent pregnancy loss of only 3%.[1] Therefore ultrasonography-proved viability between 8 to 10 weeks' gestation allows us to intervene well before the traditional 13 or 14 weeks' gestation and to do so with a 95% likelihood that the pregnancy will be maintained, barring a complication of surgery. Operation at 11 weeks' gestation is associated with less operative blood loss and can be done through a Pfannenstiel incision, which is a major advantage for the patient. At 14 or 15 weeks' gestation a vertical or transverse muscle-splitting incision is required for exposure.

We used prophylactic antibiotics, a single dose of a cephalosporin preoperatively, in addition to any earlier treatment of abnormal cervical cultures.

Improved mammographic accuracy

S. Gainer Pillsbury, Jr., MD, John S. Link, MD, and Susan Roux, MD
Long Beach, California

Use of ancillary imaging studies to evaluate suspicious screening mammograms can improve their positive predictive value for detecting malignant lesions. In 1989 8181 screening mammograms were performed at the breast evaluation center at Memorial Hospital Medical Center in Long Beach. A total of 670 patients were called back for magnification views or ultrasonographic evaluation, and 92 of these patients underwent surgical biopsy. There were 42 cancers diagnosed, yielding an accuracy rate of 46%. (AM J OBSTET GYNECOL 1991;164:1643-6.)

Key words: Screening mammography, magnification views, ultrasonography positive predictive value

The lifesaving benefits of screening mammography have been convincingly demonstrated.[1] The American College of Obstetricians and Gynecologists, the American Cancer Society, and other professional and lay groups have established guidelines for the use of this procedure.

Surveys have shown that whereas the majority of primary care physicians are aware of the guidelines and benefits of mammography, only a minority of them recommend routine mammography to their patients.[2,3] A recent survey by the National Cancer Institute demonstrated that only 25% to 41% of women over the age of 50 had had a mammogram during the previous year. One of the chief reasons for not having the procedure done was that the patient's physician did not recommend it.[3]

One of the major reasons cited by physicians for not ordering screening mammography is the cost of the procedure.[4] This refers not only to the charge for the test itself but also to the charge for the large number of additional procedures and biopsies generated by mammography, which has, until recently, had a relatively low rate of accuracy in detecting malignancy.

Reports in the literature state that the positive predictive value of mammography for malignancy ranges from 10% to 30%. A presentation by Dr. Goodno to this society last year indicated that in his community the diagnostic accuracy was approximately 14%.[5] Before the establishment of the breast center in Long Beach, the malignancy detection rate was 12%.

Methods

In 1987 a breast evaluation center was established as part of the Memorial Cancer Institute at Long Beach Memorial Medical Center. The goal was to be able to thoroughly evaluate patients with imaging modalities and other ancillary procedures at one facility.

We use dedicated film screen mammographic equipment with the ability to perform magnification views. Ultrasonographic equipment is available on site to help differentiate solid from cystic lesions. The technicians performing the procedures have received extensive training in mammography and breast ultrasonographic examinations. There is a full-time, experienced radiologist at the center who, in most cases, determines what ancillary procedures need to be performed once the patient has been examined and the mammograms reviewed.

In addition to these imaging modalities, fine needle aspiration is available. A pathologist is present to evaluate aspiration of palpable solid lesions to be certain that sufficient tissue is obtained to make a diagnosis.

Symptomatic women who are referred to the breast evaluation center because of pain, suspected mass, bloody nipple discharge, or other reasons have whatever diagnostic modalities are believed necessary, including fine needle aspiration.

Screening mammograms are also performed at the breast evaluation center. An examination consisting of a craniocaudal and a mediolateral oblique view is performed with film screen radiography. At the suggestion of Dr. Laszlo Tabar,[6] a protocol was established for the evaluation of patients with suspicious or equivocal findings on screening films. Instead of recommending surgical biopsy, we ask these patients to return for additional imaging procedures. Magnification views are used to evaluate architectural distortion or suspicious calcifications. Ultrasonographic studies are performed to differentiate solid from cystic nodular lesions seen

6/6/27949

on the screening films. Other imaging modalities such as thermography, light scans, or computerized tomography have not been used to evaluate these patients.

Results

In 1989 8181 screening mammograms were performed. Of these, 670 patients were called back for additional imaging studies. Surgical biopsy was recommended in 92 of these patients. Biopsy was performed with fine needle localization, since no palpable abnormalities could be detected. There were 42 cancers diagnosed, yielding an accuracy rate of 46%.

Comment

With the advanced technology and training available to radiologists interested in mammography, the ability to evaluate suspicious findings has been vastly improved by the addition of ancillary imaging studies, such as magnification views and ultrasonography. While these add a slight additional charge, the majority of confusing findings on screening mammograms can be more adequately evaluated. This results in a more confident radiographic diagnosis that frequently precludes the need for surgical biopsy.

It has been a European philosophy for years, advocated by Dr. Tabar,[6] that no patient should undergo operation on the basis of a two-view routine screening mammogram. The screening mammogram is only a preliminary survey of the patient. He stated that abnormalities seen on a screening study need additional imaging to determine whether they represent actual abnormality, overlapping artifacts, or classically benign abnormalities.

Improved diagnostic accuracy of mammography results in impressive cost savings. In this study approximately 8% of the patients screened were asked to return for magnification views or ultrasonographic studies. Since the additional charge for these evaluations is $65, the extra charge for the 670 patients was $39,455. Charges for a breast biopsy in our area total about $3000. The costs for the 92 patients who underwent biopsy ($276,000) plus the charges for the additional imaging studies for 670 patients total $315,455. Had biopsy been the procedure of choice to evaluate the suspicious screening radiographic findings, it would have been much more expensive, both financially and in the emotional and psychosocial stress for the patients.

Additional imaging studies were used more liberally than surgical biopsy would have been, but if we assume a 12% malignancy rate at our facility before the present protocol, approximately 350 women would have undergone a biopsy at a total cost of $1,050,000. Clearly, the use of high-quality imaging in the hands of experienced radiologists results in tremendous savings.

In conclusion, the positive predictive value of routine screening mammograms can be greatly enhanced when patients with equivocal findings are studied further with magnification views or ultrasonography. Reducing the number of unnecessary biopsies will not only lower costs but may encourage more primary care physicians to recommend this valuable cancer screening modality to their patients. Clearly, as when any consultant is used by primary care physicians, careful attention to the radiologist's experience and the quality of the equipment used is an important variable when patients are referred for these evaluations.

Discussion

DR. KEITH P. RUSSELL, Los Angeles, California. Dr. Pillsbury, how many of the mammograms were ordered by obstetrician-gynecologists? Members of our specialty have almost quadrupled their use of mammographies within the past 10 years. It is interesting that general surgeons, who consider treatment of the breast their domain, sometimes excessively in my opinion, are at the bottom of the list as far as ordering mammograms.

The information you presented may be deceptive unless it is expanded. You presented the results of >8000 mammographies and 92 biopsies, 42 of which were positive for cancer. The implication is that these 42 were the only positive results among the approximately 8000 women. However, there must have been some missed breast cancers in the women who did not have a biopsy. Although I agree that we should not be rushed into doing biopsies, I need to know if there were any missed cancers in the follow-up of those other women? The critical issue is how many breast cancers were missed. It is not enough to say that a smaller number of women underwent biopsy, and thereby we saved many dollars.

Some of the stated resistance by physicians to ordering mammography is the cost. Dr. Pillsbury, I know this unit is not in your office, but I would like to know the cost of an initial screening mammogram. Has your group considered distributing the cost of the additional workup over all of the population served and adding a small amount, perhaps $5, to the initial charge so that there would be no additional charge?

Dr. Gilbert A. Webb, San Francisco, California. I also wanted to express my concern about the lack of information on the false-negative rate of the magnification views and the ultrasonography. If you do not have the data, can you tell us what is the rate reported in the literature? In addition, can you tell us the percentage of invasive cancers versus in situ cancers in the biopsies of your cases? How many were lobular, and how many were ductal?

Dr. William Hindle, Los Angeles, California. Dr. Webb, in the screening mammography program at the Massachusetts General Hospital,[1] 35% of the diagnosed carcinomas were in situ. Before the screening program the rate was about 5%. Of course, most of those are ductal carcinomas.

REFERENCE

1. Kopans DB. Preoperative localization of nonpalpable breast lesions. Curr Opin Radiol 1989;1(2):200-2.

Dr. John A. Goodno, Arcadia, California. Dr. Pillsbury, you are to be commended for using a dedicated radiologist to read all the mammograms in the breast center you established. I hope that other gynecologists will establish community breast centers.

Dr. Ronald P. Millard, Bellingham, Washington. A radiologist who limits his practice to mammography asked if we would be interested in having his technician and equipment come into our office once a week to offer mammography. We agreed to try it because both the radiologist and his equipment have good reputations and the charge is only $65 for the screening and $20 for any follow-up. I believe that compliance on screening mammography has been virtually 100%. Our patients are delighted; they are more comfortable in their gynecologist's office than in a radiologist's office to which they had never before gone.

Dr. J. Paul Shively, San Francisco, California. A van from the radiology department of the University of California, San Francisco, goes out on a schedule to various neighborhoods. The cost for routine mammography is low, initially $30 and currently $50, and the service is magnificent. They telephone our office the next day to report any suspicious screening film, and they report the need for magnification imaging, ultrasonography, or biopsy.

Dr. Charles F. Langmade, Pasadena, California. You are very fortunate to have the same radiologist study all of your mammograms. Many of us get reports from several radiologists, depending on where the patient lives. Do you have any suggestions for dealing with the problem of the defensive medicine practiced by some radiologists who overinterpret mammograms and pathologists who overinterpret the slides?

Dr. Pillsbury (Closing). Dr. Russell, I do not have data on how many mammograms were ordered by obstetrician-gynecologists, but I suspect most of them were.

The current charge for a screening mammogram at the breast evaluation center is $95. To minimize the cost of the procedure, the screening is performed by technologists, and the films are read in a batch later the same day or the next day. Thus women with suspicious findings must be called back. The extra charge for either an ultrasonographic examination or a magnification view is $65. It is a provocative suggestion to include the cost of these additional tests required by about 8% of women (670/8180) in the charge for the screening mammogram, but I do not know whether that is possible with the present systems of reimbursement.

With any screening test one must be concerned about both sensitivity and specificity. One wants a screening test to be very sensitive so it doesn't miss any abnormalities. It is about the sensitivity of our protocol that both you and Dr. Webb expressed concern. You asked how many of the 670 women with suspicious mammograms would have had cancers not diagnosed by the management strategy we used had all of them had a biopsy. I do not have the data on the rate of false-negative results with this protocol, since not enough time has gone by to detect cancers that may have been missed. One encouraging fact is that the total number of cancers detected is what one would expect from a comparable group. Among 1000 women over the age of 50 not screened before, you should expect to find seven cancers.[1] Among previously screened women the rate is 3 or 3.5. We detected 42 cancers in a group of 8180 women, some of whom had previously been screened, for a rate of about 5 per 1000, which falls within that range.

Dr. Goodno and Dr. Millard, I believe the trend toward performing mammograms in the gynecologist's office is a good one. Anything we can do to make the procedure more convenient will enhance compliance. For a number of years I have found that many patients do not get the mammograms I order. Just as in the television commercials, they say, "I didn't have time." Now I can say, "Just go right across the hall and get it now." I think this is a tremendous help for patients. We need to be certain, however, that the films taken are of high quality and are read by experienced mammographers. In our office we now have a machine and a full-time technologist. In the interest of quality control, we develop the film and then have a radiologist interpret it. We charge $100, $5 more than the screening center charges.

Dr. Shively mentioned another way to increase compliance. If we are truly concerned about the health care of women, we should be alarmed by the knowledge that 60% to 80% of eligible women do not get screening mammography. We know that 7 of 1000 women who have never been screened have breast cancer. Let us try to encourage patients to get regular screening mammograms. We can detect early malignancies at a time when the vast majority of the patients can be cured.

Dr. Langmade, we need to encourage our radiologists to be true consultants, sharing the responsibility for making a definite diagnosis. Screening for breast cancer is a team effort. In private practice we direct patients to our consultants. We find radiologists who will give us meaningful reports and act as true consultants. There are some mammographers whom we never use because their reports are full of equivocations and disclaimers. They try to make the responsibility all ours. We encourage our mammographer to state that the mammogram is normal and needs to be repeated only at routine intervals or, if it is abnormal, to state which additional study or biopsy is indicated. This is the mark of a real consultant.

Conservative management of breast fibroadenomas

William H. Hindle, MD, and Leopoldo J. Alonzo, BS
Los Angeles, California

Is it conservative or radical management to excise all fibroadenomas of the breast, especially in women <30 years old? Once a definite diagnosis is established by physical examination, fine-needle aspiration cytologic testing, and mammography, is it prudent to monitor women with small fibroadenomas (<4 cm in diameter)? We reviewed 498 cases of biopsy-proved fibroadenomas and 17 cases of phyllodes tumors (by biopsy) seen at Los Angeles County/University of Southern California Medical Center from 1986 to 1989. Analysis of patient age and measured tumor size in 203 fibroadenomas and 10 phyllodes tumor specimens revealed similar ranges for both tumors. The mean values were 28.5 years and 2.3 cm for fibroadenomas and 44 years and 3.8 cm for phyllodes tumors. No cases of coincident carcinoma within a fibroadenoma or of metastatic malignant phyllodes tumors were present in this review. As an alternative to excising all breast tumors, cytologically diagnosed fibroadenomas can be monitored, because they have no intrinsic premalignant potential and tend to regress with time. All breast tumors that rapidly increase in size should probably be excised at any age. (AM J OBSTET GYNECOL 1991;164:1647-51.)

Key words: Breast fibroadenoma, phyllodes tumors

Fibroadenomas are the most common benign tumors of the breast. Fine-needle aspiration cytologic testing is accurate and dependable for diagnosing fibroadenomas.[1,2] The cytologic criteria for distinguishing fibroadenomas from cancers and phyllodes tumors have been established.[3,4] Although coincident cancers do occur within fibroadenomas,[5] fibroadenomas per se are not premalignant.[6]

The clinical presentation of fibroadenoma is distinctive from cancer and phyllodes tumors. However, the definitive diagnosis must be established by fine-needle aspiration cytologic testing or histologic features on open surgical biopsy.

Must all fibroadenomas be removed by total surgical excision? Can cytologically diagnosed fibroadenomas prudently be monitored and not removed[7]? What is being achieved by the removal of all fibroadenomas? What is the cost/benefit ratio of this traditional surgical approach? What is the risk of not removing fibroadenomas? Evaluation of the Los Angeles County/University of Southern California Medical Center surgical experience for 1986 through 1989 sheds some light and suggests a conservative though provocative nonsurgical approach, to be tested by future clinical trials.

Material and methods

Computer survey of all the surgical pathology reports of breast biopsies performed in the Los Angeles County/University of Southern California Medical Center from 1986 to 1989 revealed 489 cases of fibroadenomas and 17 cases of phyllodes tumors of the breast. The age of the patient was available in all cases, but detailed specific data as to pathologic measurements of the tumors were available on only 203 fibroadenomas and 10 phyllodes tumors. Selection bias is possible because of the number of tumors that did not have precise measurements recorded in the pathology report.

Results

No coincident in situ or infiltrating cancers within fibroadenomas and no metastatic phyllodes tumors were identified. The phyllodes tumors were 3% of the total group, with a ratio of phyllodes tumors to fibroadenomas of 1:29. The patients with phyllodes tumors had a mean age of 44 years with a range of 19 to 75 years. The mean tumor size was 3.8 cm with a range of 1.5 to 8.0 cm.

The patients with fibroadenomas had a mean age of 28.5 years with a range of 12 to 65 years (Fig. 1). The mean tumor size was 2.3 cm with a range of 0.5 to 6.5 cm (Fig. 2). The 12-year-old girl had a 4 cm tumor, and the 65-year-old woman had a 0.9 cm tumor. There was a 9.5 cm juvenile giant fibroadenoma in a 16-year-old girl; it is not included in this analysis. There is a trend toward decreasing mean size with increasing age (Fig. 3).

Comment

Treatment of breast tumors should be individualized. Options for methods of treatment should be discussed with each patient and clear, complete informed consent obtained. The choice of treatment should be a responsibly shared decision between the patient and her physician. Fear of cancer and death is a paramount anxiety in women with breast tumors, but benign lesions can be monitored with regular clinical breast examinations and mammography. Between each follow-up visit, the patient should be doing thorough, regular breast self-examinations. As with all dominant breast masses, a

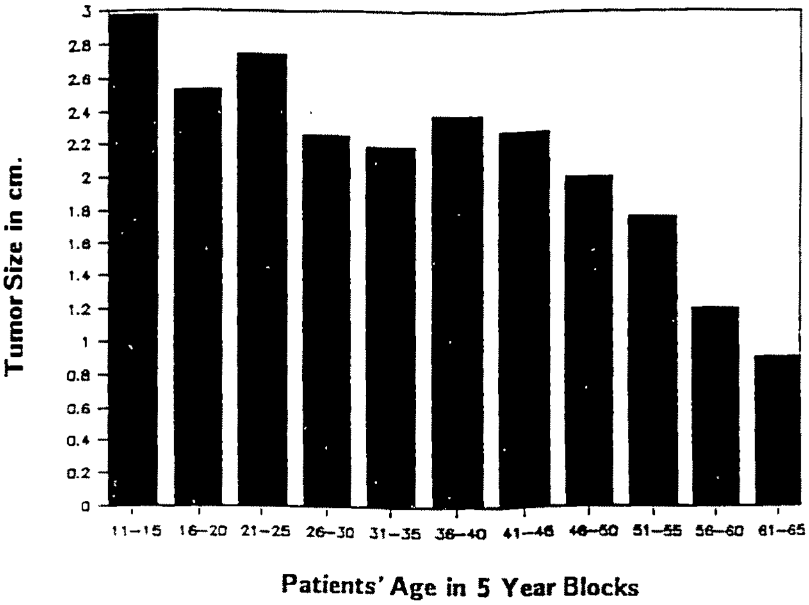

Fig. 3. Mean tumor size by measurement recorded in pathology reports of 203 fibroadenomas versus patient age in 5-year blocks.

definitive diagnosis must be established by fine-needle aspiration cytologic testing or by histologic features on open surgical biopsy.

Because of the widely overlapping ranges, the patient's age and the tumor size are not clinically reliable in differentiating fibroadenomas from phyllodes tumors. Rapid change in tumor size may be a distinctive clinical characteristic of malignant phyllodes tumors,[8,9] although fibroadenomas can increase rapidly in size during pregnancy and potentially with exogenous estrogen stimulation.

Clinically, fibroadenomas often stabilize in size at about 2 to 3 cm.[10,11] Fibroadenomas are reported to regress and resolve in significant numbers.[10,12,13] Serial mammography confirms that with aging of the patient fibroadenomas usually decrease in size, can infarct, and often calcify.[14,15] Fibroadenomas are not commonly found during autopsies or in mastectomy specimens of postmenopausal women.[12,16,17]

Phyllodes tumors have clinically been described as large (>4 cm at presentation) and rapidly growing. Phyllodes tumors are pathologically classified by established criteria as benign or malignant, although the pathologic distinction can be imprecise.[18] Although 20% of the pathologically benign tumors recur locally, they do not metastasize.[19] Twenty-six percent of the pathologically malignant tumors recur locally and 20% metastasize.[19] The usual treatment is wide excision of benign tumors and total mastectomy for malignant tumors.[20]

Future clinical research with careful follow-up after fine-needle aspiration cytologic diagnosis of fibroadenomas should be undertaken to assess the effectiveness and safety of the nonsurgical approach to fibroadenomas, to evaluate the potential decreased physical and emotional trauma to the patient, and to calculate the potential decreased health care cost.

Discussion

DR. ROGER W. HOAG, Berkeley, California. I voice a cautionary note. As we appear to be at the turning point of winning the war in the "bad baby" cases, our malpractice committees predict that the new target of the plaintiffs' attorneys will be the misdiagnosis or the delayed diagnosis of breast cancer. We are improving our skills with needle biopsy and mammography. However, if we are wrong and one of these persistent nodules turns out to be malignant, we are going to be very wrong. I have reviewed several cases in which the doctor monitored a nodule, thinking it was benign; one case was based on mammography and one case was based on a fine-needle aspiration showing a benign process. Many general surgeons who deal with breast cancer feel that if there is a mass in the breast, a report of "not cancer" on a fine-need aspiration is not sufficiently negative. We should be very careful in the next few years as these questions are debated, both in clinical meetings such as this and in the courts.

DR. CLYDE V. VON DER AHE, Los Angeles, California. I know that you have a rapid staining method and can determine, while the patient is still in the clinic, whether you are dealing with a benign or a malignant lesion. Do you recommend that the private physician practicing in an office without that ability who aspirates straw-colored clear fluid send it to a pathology laboratory to get a report stating that there are no malignant cells or simply dispose of the fluid in the sink and tell the patient it is benign? Of all the breast cysts that I have aspirated, only one cytologic result was even questionable.

DR. JACK G. HALLATT, Los Angeles, California. The value of mammography is not in question, but it is not available to some and not used by many. I tell my patients to examine their breasts whenever they bathe or shower. It takes practice to get acquainted with the normal breast tissue sufficiently to distinguish it from abnormal tissue, and I do not think it can be learned by the usually recommended once-a-month examination. Breast examination in the shower helps to overcome the emotional reluctance on the part of many women to examine their breasts. Moreover, the slipperiness of the soap film makes any abnormality stand out. Dr. Hindle, what do you feel is the value of self-examination?

DR. HINDLE (Closing). Dr. Hoag, my experience in reviewing medicolegal cases involves reviewing about one case a month and testifying in court. The best defense is to follow the guidelines, do regular examinations, and record your examinations. Absolutely every palpable mass must be diagnosed without delay. Triage of a palpable breast mass is with a needle because you immediately know, if it is a cyst, it has a 99.99% probability of being benign. If it is a solid mass, you can do fine-needle cytologic testing and obtain a specific cytologic diagnosis, for example, fibroadenoma. Without a diagnosis you have no protection. With physical examination, mammography, and fine-needle aspiration, you can specifically diagnose 90% of benign or malignant masses that are palpable in the breast. Only 10% require open biopsy. In this situation we should stop using the word *negative.* There is no such thing as a negative fine-needle aspiration or a negative mammogram. I am speaking here of diagnostic mammography used for work up in a woman with a breast problem, especially a mass. This is different from the screening mammography used for asymptomatic women.

Dr. Von Der Ahe, you can dispose of an aspirate containing clear cyst fluid provided you do two other things: make sure there is no residual mass and examine the patient to see if the cyst recurs. You need to see the patient again at 1 month and at 3 months. If there is no residual mass, if the fluid is clear or straw-colored, not bloody, and if the cyst does not recur in 3 months, the patient can return to a routine screening schedule because she is at no higher risk for breast cancer than other women her age. Bloody fluid should be sent for cytologic testing, although the incidence of carcinoma is $<1:1000$. You may have a problem if your pathologist is likely to report atypical cells. This creates a problem because you will have to do a biopsy, and that process is not cost-effective.

It is generally recognized that treatment of breast disease is a multispecialty team effort, and it is now becoming obvious that the diagnosis of breast disease is also a team effort. You must be able to talk in mutually understandable terms with your mammographer and surgeon before the biopsy and with the pathologist and cytopathologist after you do the fine-needle aspiration.

Dr. Hallatt, there are no data to show that breast self-examination done more often than once a month is any more effective. The most important thing is to do it, whatever method one uses. Women who do breast self-examination tend to have slightly earlier-stage cancer when detected. However, the average breast cancer found by self-examination is 2.5 cm, an inch, in diameter.[1] At that stage, 50% have positive nodes and 50% will die of disease.[1] I encourage every patient to do breast self-examination. When you go into court, you should have documentation in your chart that you told the patient that, not only once but every time she came back. It helps if you have shown them videos and given them handouts, but it is most important that someone has demonstrated the technique to the patient and that she has demonstrated that she has learned it.

Although breast self-examination programs will not greatly change the mortality from breast cancer, teaching breast self-examination does lead to patient awareness and willingness to participate in screening projects that are truly effective in reducing mortality. The cure rate for women with nonpalpable breast cancer <1 cm in diameter, found with screening mammography and subsequently treated, is 95% at 10 years.

When the American Cancer Societey says that one out of 10 women will get breast cancer, it does not mean you can look around a crowded room and expect that breast cancer will devlop in 10% of the women. That statistic is the cumulative life risk in the United States for a white woman who lives to be 110 years old. If you are already 50 and are free of cancer, your risk is down to <5%.[2]

Fetal choroid plexus cysts in the second trimester of pregnancy: A cause for concern

Lawrence D. Platt, MD, Dru E. Carlson, MD, Arnold L. Medearis, MD, and Catherine A. Walla, RN, MA, MN
Los Angeles, California

Controversy surrounds the issue of recommending cytogenetic studies in second-trimester fetuses with fetal choroid plexus cysts. To assist in clarifying this issue, a prospective study was designed to describe the association between fetal choroid plexus cysts and aneuploidy in a large population. During a 3-year period 7350 women at 15 to 22 weeks' gestation underwent an ultrasonographic evaluation. Fetal choroid plexus cysts were diagnosed in 71 (0.96%) of these pregnancies. Sixty-two of the 71 patients elected to undergo amniocentesis. An abnormal karyotype was identified in four (6.4%) of these fetuses. One fetus had trisomy 21, and three fetuses were diagnosed with trisomy 18. These data indicate that it is reasonable to offer genetic counseling and cytogenetic studies in those patients identified as having a fetal choroid plexus cyst. (AM J OBSTET GYNECOL 1991;164:1652-6.)

Key words: Choroid plexus cysts, aneuploidy, ultrasonography, cytogenetic studies

Recent investigations have demonstrated that various ultrasonographically visualized dysmorphic features can be used as suggestive markers in the diagnosis of the aneuploidic fetus. These features include abnormalities of the hands, feet, and limbs,[1-5] abnormalities of the face and head,[3] diaphragmatic hernia,[3] thickened nuchal skin folds,[6] congenital heart defects,[7, 8] and choroid plexus cysts.[8-10] The last of these, fetal choroid plexus cysts, has been found to be especially controversial as a morphologic variant that may be associated with aneuploidy, specifically trisomies 18 and 21.

Cysts of the choroid plexus of the lateral ventricles (Fig. 1) are relatively common in all age groups, are usually asymptomatic, and rarely produce complications.[11, 12] These cysts were initially identified in the neonate with real-time ultrasonography in 1981.[13] It was not until 1984, however, that Chudleigh et al.[14] first described this finding in the second-trimester fetus. In general, fetal choroid plexus cysts can be visualized in the late first and early second trimesters. They appear as echolucent structures, have sharply circumscribed margins, are typically <1 cm in diameter, may be either unilateral or bilateral, and usually disappear completely or significantly decrease in size by 24 to 26 weeks' gestation.[15-19] The incidence of fetal choroid plexus cysts has varied among investigators, ranging from 0.18% to 2.5%,[15, 19-22] having an average incidence of approximately 1% in all second-trimester fetuses with these cysts.[23] It is generally agreed that the majority of choroid plexus cysts are benign; however, several reports have associated cysts with chromosomal abnormalities. Both prospective and retrospective studies investigating this finding have reported on a relatively small number of cases. In addition, they reflect varied sample selection criteria, including a wide distribution of gestational ages from first- to third-trimester fetuses, and have, at times, presented anecdotal data.[8-10, 15-18, 20-23] Because of the differences among these studies, it is difficult to determine whether choroid plexus cysts do indeed have a relationship with aneuploidy. To better clarify this controversy, this report describes a prospective study, the purpose of which was to determine if an association can be demonstrated between choroid plexus cysts and chromosomal abnormalities, specifically trisomies 21, 18, and 13, in second-trimester fetuses.

Material and methods

During a 3-year period ranging from January 1987 to January 1990, 7350 women between 15 and 22 weeks' gestation underwent ultrasonographic evaluation at Cedars-Sinai Medical Center, Children's Hospital of Los Angeles, or Women's Hospital, Los Angeles County–University of Southern California Medical Center. Indications for these examinations included advanced maternal age, gestational age determinations, second-opinion ultrasonographic evaluation of a previously described abnormality, and maternal anxiety. Any women referred because of choroid plexus cysts

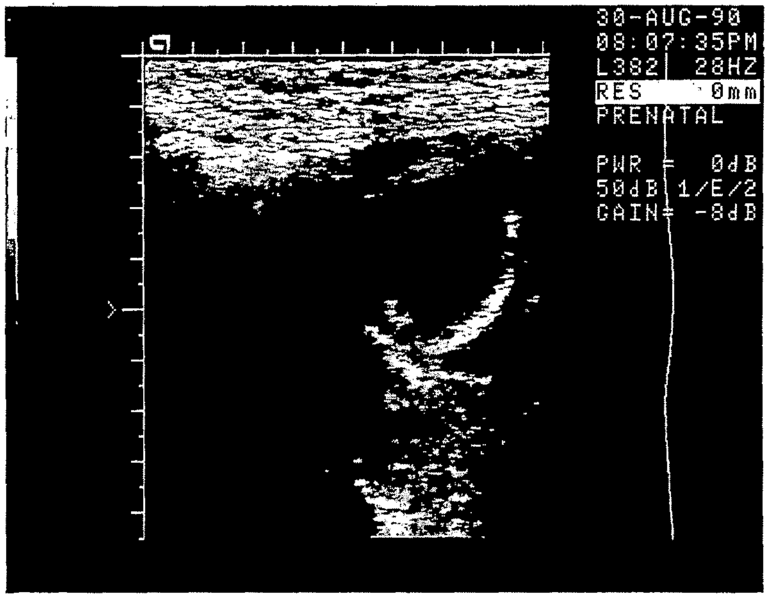

Fig. 1. Ultrasonography demonstrates presence of small, complex choroid plexus cyst.

were excluded as study patients. We performed all scans, which were done with a state-of-the-art, real-time ultrasonographic system with 3.5 to 5 MHz sector or linear transducers. Evaluations included morphometric measurement to determine gestational age, examination of the choroid plexus for the identification and measurement of a cyst, and extensive examination to detect any structural malformations. If a choroid plexus cyst was diagnosed, the patient was scheduled for a repeat ultrasonographic examination at 22 weeks. A follow-up evaluation was done at 34 weeks' gestation if the cyst was present at the time of the second examination. As a result of the diagnosis of fetal choroid plexus cyst, all women either were scheduled to undergo amniocentesis or were offered amniocentesis. Cytogenetic diagnoses were made either at the time of amniocentesis or, in those patients who declined the procedure, at the time of delivery if a dysmorphic fetus was identified.

Results

Among the 7350 women having a second-trimester ultrasonographic evaluation, fetal choroid plexus cysts were diagnosed in 71 pregnancies, an incidence of 0.96%. Fifty-eight (81.7%) of these cysts were unilateral, whereas 13 (18.3%) were bilateral. Sixty-two of the 71 patients elected to undergo amniocentesis. An abnormal karyotype was identified in four (6.4%) of these fetuses (Table I). One (1.6%) fetus had trisomy 21, and in three (4.8%) other fetuses trisomy 18 was diagnosed. Both the patient with trisomy 21 and one of the three with trisomy 18 were originally scheduled to undergo amniocentesis for previously abnormal ultrasonographic examinations.

Table I. Incidence of fetal choroid plexus cysts in relation to aneuploidy in second-trimester pregnancies

Total no. of patients scanned		7350
Fetal choroid plexus cysts identified		71 (0.96%)
Amniocenteses performed		62
No. of fetuses with aneuploidy		4 (6.4%)
Trisomy 21	1	
Trisomy 18	3	
Trisomy 13	0	

In all four aneuploidic fetuses, additional structural malformations were diagnosed by ultrasonography at the study centers. An atrioventricular canal defect was detected in the fetus with Down syndrome diagnosed. Abnormalities identified in the trisomy 18 fetuses included: (1) clenched hands, ventricular septal defect, omphalocele, and ventriculomegaly; (2) clenched hands, complex heart defect, and intrauterine growth retardation; and (3) ventricular septal defect (Table II).

Two of the women with aneuploidic fetuses subsequently terminated their pregnancies. The two remaining women with cytogenetically abnormal fetuses decided to continue their pregnancies. Fetal death occurred at 30 weeks' gestation in one of these patients, and the second was delivered at term. This neonate died eight days after birth of a congenital heart defect.

All women who continued their pregnancies were rescanned at 22 weeks' gestation. Persistent cystic

Table II. Ultrasonographic findings of aneuploidic fetuses with choroid plexus cysts

Case No.	*Chromosomal abnormality*	*Other ultrasonographic findings*
1	Trisomy 21	Atrioventricular canal defect
2	Trisomy 18	Clenched hands, ventricular septal defect, omphalocele, ventriculomegaly
3	Trisomy 18	Clenched hands, intrauterine growth retardation, complex heart defect
4	Trisomy 18	Ventricular septal defect

changes were visible in only six (5.8%) of 69 women (the 67 normal patients and the two with aneuploidic fetuses who did not terminate their pregnancies). These six cysts were completely resolved by 34 weeks' gestation. The sixth fetus died in utero, at 30 weeks' gestation.

In the 62 patients who underwent amniocentesis, all were delivered at ≥34 weeks' gestation, except for the trisomy 18 fetus that died at 30 weeks. No differences in fetal and neonatal outcome were identified between what has previously been described as complex cysts and simple cysts. Additionally, no differences in outcome were found between unilateral and bilateral cysts.

Comment

A number of studies have reported an association between fetal choroid plexus cysts and aneuploidy, particularly trisomy 18. Because of this association, it has been suggested by various researchers that cytogenetic studies be offered when these cysts are diagnosed. This recommendation is particularly inviting since several investigators[9, 10, 15, 22] have reported the presence of fetal choroid plexus cyst in aneuploidic fetuses when no other structural abnormalities were visualized ultrasonographically.

In this current study no aneuploidic fetus was noted to have a choroid plexus cyst without any other dysmorphic features identified. Of the four fetuses diagnosed with chromosomal abnormalities, however, one (25%) was detected ultrasonographically with only the diagnosis of a ventricular septal defect.

The incidence of congenital heart disease among trisomic disorders has been demonstrated to be very high. Fetuses with trisomy 21 have been reported to have a 50% incidence of cardiac anomalies. Those fetuses with trisomies 13 and 18 have a 90% and 99% incidence, respectively, with the most common of cardiac defects associated with all three disorders being ventricular septal defect.[24] A recent study has demonstrated that approximately 90% of aneuploidic fetuses were diagnosed prenatally by fetal echocardiography.[25] However, ventricular septal defects are less than optimally visualized in the second-trimester fetus,[26] especially by the less experienced ultrasonographer.

Despite the many articles advocating cytogenetic studies, the recent report by Benacerraf et al.[23] suggests that when the expected risk of amniocentesis versus the expected yield of an abnormal result is calculated, amniocentesis is not indicated when no structural malformations other than a fetal choroid plexus cyst are observed with ultrasonography. While the data in this report also demonstrate that other structural malformations were indeed seen in each of the fetuses diagnosed with aneuploidy, one patient was diagnosed with only the identification of a ventricular septal defect. However, this heart defect was sufficiently small to allow us to speculate that had optimal imaging conditions not been present, this lesion may have been overlooked by us, as well as by most ultrasonographers.

Additionally, in raising the question of the actual diagnostic value of fetal choroid plexus cysts in relation to the identification of aneuploidy, Benacerraf et al.[23] have reported a value of 30% for the sensitivity of choroid plexus cysts for detecting trisomy 18 and a positive predictive value of 0.9%. These low values appear to indicate that choroid plexus cysts are an ineffective indicator in the detection of chromosomal abnormalities. There are, however, no prospective studies that have evaluated the sensitivity, specificity, or positive and negative predictive values of the diagnosis of all malformations on ultrasonographic examination in the second trimester. Until such time that these data are available, it seems that using statistical methods for risk benefit must be limited. This type of analysis is further limited by the fact that common structural anomalies coexisting with aneuploidy, particularly congenital heart defects, may be missed.

A similar situation involves the sensitivity of ultrasonography in the diagnosis of neural tube defects. Nadel et al.[27] and Richards et al.[28] have suggested that in patients with a family history of a neural tube defect or with an elevated maternal serum α-fetoprotein level an experienced ultrasonographer is likely to rule out the vast majority of the defects. Thus, according to these authors, amniocentesis for maternal serum α-fetoprotein analysis for open neural tube defects may not be warranted. While we believe that this may have merit in some ultrasonographic hands, it may not be ready for adoption as a universal policy.

In conclusion, since the fetal head undergoes closer scrutiny by the ultrasonographer than does almost any other fetal structure, it is likely that the fetal choroid plexus cyst will be more commonly identified than other smaller defects. Once this anatomic variant is recognized, the patient should be offered, at a minimum, a second-opinion ultrasonographic examination. However, because of the data and issues presented in this report, we believe that until proper prospective studies are carried out with regard to the sensitivity and specificity of ultrasonographic diagnosis of chromosomal abnormalities in the general population and not just the "ivory tower," patients with fetal choroid plexus cysts identified should be offered genetic counseling and cytogenetic studies of the fetus by the least risky method.

Discussion

DR. ROBERT J. LOWDEN, Seattle, Washington. Dr. Platt, you did a tremendous amount of work by reviewing 7350 ultrasonographic examinations in preparing this article. The largest similar series I found in the literature involved 6288 cases.[1] Among 7350 examinations of second-trimester patients, you found 71 fetuses with unilateral or bilateral choroid plexus cysts. Of these, 62 were subjected to amniocentesis, and four fetuses had an abnormal karyotype—one trisomy 21 and three trisomy 18. In all four an additional structural malformation was identified. In all but four of the other patients who continued their pregnancies and were scanned again at 22 weeks, the cystic changes were no longer visible. In these remaining four all cysts were gone by week 34.

Choroid plexus cysts have been identified in 1% to 3% of scans by Benacerraf et al.[2] and by Chinn et al.[3] Both felt these cysts were transient and of no clinical significance, although some were associated with trisomy 18. Chitkara et al.[1] detected choroid plexus cysts in 40 fetuses between 16 and 42 weeks' gestation. Of these, 33 resolved by 22 to 24 weeks and another four by 26 to 28 weeks. Approximately half were bilateral. One fetus with bilateral cysts and additional abnormalities had trisomy 18. Chitkara et al. strongly recommended chromosomal studies whenever associated anatomic abnormalities are detected and whenever the cysts are large, bilateral, or present after 20 to 22 weeks' gestation. Kirschbaum,[4] in his review of the article, stated that it remained to be established that choroid plexus cysts and chromosome abnormalities were more than coincidentally related.

Chinn et al.[3] reported on 13 fetuses with choroid plexus cysts among 513 women who underwent genetic amniocentesis between 16 and 24 weeks' gestation. Approximately one third of the cysts were bilateral. All 13 fetuses had normal karyotypes. Conversely, of 500 fetuses without choroid plexus cysts, five had trisomy 21 and two had trisomy 18. Benacerraf et al.[2] noted that if genetic amniocentesis was done in all second-trimester pregnancies with no ultrasonographic abnormalities other than fetal choroid plexus cysts, 478 procedures would have to be done to identify one case of trisomy 18. Clark et al.[5] in Salt Lake City found fetal choroid plexus cysts in five fetuses among patients having second-trimester ultrasonography for standard obstetric indications during a 2 year period, an incidence of 0.18%. Two cases were bilateral. No additional abnormalities were detected. All cysts had disappeared on follow-up 2 to 5 weeks later. Pregnancies continued normally and all infants were physically and neurologically normal at birth and between 4 and 24 months of age. These authors[5] concluded that in the absence of additional abnormalities and with normal sequential fetal growth, the value of routine fetal karyotyping for this indication remained undefined.

Dr. Platt, your article is informative and provocative. I agree with your point that finding a choroid plexus cyst associated with other developmental abnormalities indicates the need for a complete chromosomal study. However, on the basis of the evidence just cited, I disagree with your conclusion that the presence of choroid plexus cysts alone requires amniocentesis and further workup.

Please comment on the following. In our clinic the cost of ultrasonography, amniocentesis, and genetic workup is about $1000, on top of the cost of the usual obstetric care. Can the medical insurance industry tolerate the increased cost of care? Is there a basis for litigation if each patient does not have a workup as you advise?

DR. FREDERICK W. HANSON, Sacramento, California. Our experience has been similar. I do not think we have had a single chromosomal abnormality in a fetus with a choroid plexus cyst without some other structural abnormality seen on ultrasonography. We have seen cysts persist as late as 28 weeks.

Dr. Platt, do you have a protocol for management of cases with choroid plexus cysts and normal amniocentesis results, normal amniotic fluid α-fetoprotein and acetylcholinesterase levels, and no other structural abnormalities seen on ultrasonography? Do you feel that there is a need for any follow-up? We now plan not to repeat the scan in patients with choroid plexus cysts <1 cm in diameter who have normal findings on amniocentesis and a level 2 ultrasonographic examination showing no other structural abnormalities.

DR. PLATT (Closing). Dr. Lowden, insurance companies pay for amniocentesis for women aged ≥35, and doing the procedure is the standard of practice for this indication. Amniocentesis for women whose fetuses have choroid plexus cysts has a higher yield of diagnoses of trisomy and should be more cost-effective. In our field we are subject to litigation by simply opening the doors of our offices. As a result, since the literature points out that some choroid plexus cysts are associated with chromosomal problems, we have the obligation to inform our patients of this relationship and offer amniocentesis. Whether the couple accepts the recommendation is entirely up to them.

Unpublished data from the California maternal serum α-fetoprotein program, which was discussed by Dr. Hanson, support my position. The recent article by Nadel et al.[1] in *The New England Journal of Medicine* suggests that when there is a high maternal serum α-fetoprotein level and a normal ultrasonographic examination, it is not cost-effective to do an amniocentesis. I believe we must realistically assess our capabilities. Ultrasonography is not a perfect science. We all will make mistakes, and even the most experienced will not be able to identify all malformations. Therefore, if we identify one of these clues to the detection of malformation, I think we need to give it careful attention.

Dr. Hanson, we first must recognize that the minute we tell the patient that her fetus has a choroid plexus cyst, her anxiety level goes through the ceiling. We have to do all we can to try to lower it by explaining that most of the cysts go away by 22 weeks. Therefore all these patients are seen by our genetic counselors, and we scan them again at 22 weeks. If the cyst persists, we offer them consultation with a pediatric neurosurgeon, who tends to lower their anxiety by telling them that these cysts are in most instances benign. We look again at 34 weeks to be sure they have not grown large enough to cause obstructive hydrocephalus. Fortunately, none of our benign choroid plexus cysts have persisted to that time.

Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero

Russell K. Laros, Jr., MD,[a] Joseph A. Kitterman, MD,[b] David C. Heilbron, PhD,[c] Ronald M. Cowan, MA,[c] and William H. Tooley, MD[b]
San Francisco, California

In this study we examined neonatal and early childhood outcomes after intrauterine exposure to β-sympathomimetic agents on infants with birth weights ≤1500 gm. The hospital courses and anthropomorphic, developmental, and neurologic development of 201 infants exposed to one or more β-sympathomimetic agents (isoxsuprine, 33; ritodrine, 70; terbutaline, 43; combination, 55) were analyzed and compared with those of 130 control infants of similar birth weight. One hundred and seventy-seven infants had follow-up to 1 year of age, 101 to age 3, and 58 to age 4. When treatments consisting of a single β-sympathomimetic or no treatment were compared, there were no statistically significant overall differences found in growth and development or in most of the short-term measures of infant well-being. However, significant overall differences with no evidence of confounding by time-related effects were found for the following: mortality, none greater than terbutaline; maximum positive inspiratory pressure when respiratory distress syndrome was present, none greater than terbutaline; neonatal trauma, terbutaline greater than ritodrine. Other differences were found in conjunction with evidence of time-related confounding, or within specific time intervals. It should be noted that these differences are not necessarily due to effects of the different treatments, as the data are observational. (AM J OBSTET GYNECOL 1991;164:1657-65.)

Key words: Low birth weight, β-sympathomimetics

Currently, β-sympathomimetic agents are widely used to inhibit premature labor.[1-4] In the United States ritodrine and terbutaline are currently the most popular agents. In the past isoxsuprine also was used. However, the recent withdrawal of the parenteral form of isoxsuprine from the market and its higher incidence of undesirable side effects will markedly limit its use in the future.

While there is a considerable body of literature describing side effects of the various β-sympathomimetics on the mother, data on short-term and long-term side effects on the infant are limited,[5-11] with the most information being available for ritodrine.[9, 10] Follow-up data for infants exposed to terbutaline in utero are few.[5-12]

The purpose of this study is to carefully evaluate possible adverse effects of β-sympathomimetic agents on preterm infants with birth weights of ≤1500 gm.

Material and methods

The Department of Obstetrics, Gynecology, and Reproductive Sciences has maintained a computerized perinatal data base since Nov. 1, 1975. The data base contains 300 items of information about each mother and infant delivered at our institution. It was scanned to identify all mothers delivered of infants ≤1500 gm through Dec. 31, 1983. Over this same period the Department of Pediatrics maintained a pediatric follow-up data base containing data from the immediate newborn period and from periodic follow-up visits. The two lists of cases identified in the data bases were compared, and a final list of infants with data residing in both files was generated. Only pediatric follow-up assessments through age 4 are considered in this analysis, because later assessments had small effective sample sizes (<50) that did not represent all three of the β-sympathomimetics under study.

Although the definitions of most of the items used in this analysis are apparent, several require explanation. Whenever the gestational age by history differed from the gestational age by obstetric assessment >2 weeks, the entire maternal and neonatal records were reviewed and a final gestational age was assigned by one of the authors (R.K.L.). If the patient had a prenatal visit and pelvic examination during the first 12

weeks of gestation and the gestational age agreed with the uterine size, the last menstrual period was used to determine the final gestational age. If these criteria were not met but an ultrasonographic examination had been performed during the first 20 weeks of gestation, the gestational age determined by ultrasonography was used to assign the final gestational age. If neither of these criteria was met, the gestational age by pediatric assessment[13] was used for the final gestational age. To assess clinical severity of illness in the neonatal period, each infant was given a score (illness index) ranging from 1 (no illness) to 7 (near-fatal episode[s]), as previously described.[14]

The diagnosis of the respiratory distress syndrome (RDS) (hyaline membrane disease) was based on standard clinical[15] and radiographic[16] criteria. Data for ventilatory treatment were obtained from the patients' medical records. An air leak was diagnosed if the patient had radiographic evidence of pneumothorax, pneumomediastinum, pneumopericardium, or pulmonary interstitial emphysema. Patent ductus arteriosus was diagnosed on clinical and echocardiographic criteria and was classified as absent, present but requiring no treatment, present and treated with indomethacin, present and surgically ligated, or present and treated both medically and by surgical ligation. The diagnosis of intraventricular hemorrhage was based on findings of either ultrasonographic or computerized tomographic scanning of the brain. Necrotizing enterocolitis was classified as absent, abdominal distention (suspected), intramural intestinal gas, or perforated bowel. Sepsis was diagnosed by a positive blood culture. Hypoglycemia was diagnosed by a blood glucose concentration <30 mg/dl. Trauma included the occurrence of nerve injury, fracture, laceration, or bruising. Caloric intake during the first 2 weeks of life was calculated from both enteral and parenteral feedings. The highest indirect bilirubin was the highest value recorded during the infants' hospitalization, and the highest peak inspiratory pressure was the highest ventilator setting used in the treatment of RDS.

For pediatric follow-up, each baby's age was calculated from an adjusted birth date of 40 weeks after last normal menses. The schedule of follow-up examinations is shown in Table I, and the data recorded at each visit are in Table II.

Each maternal chart was reviewed and the various data items listed in Table III abstracted. Our standard routine for the administration of β-sympathomimetics was to begin treatment with an intravenous infusion that was continued either until uterine contractions had been eliminated for 12 to 24 hours or until delivery was imminent. If and when uterine activity was controlled, oral medication was begun 1 to 2 hours before the infusion was stopped and then repeated every 1 to 4 hours. The starting intravenous infusion rates were 10 μg/min for terbutaline, 50 μg/min for ritodrine and 250 μg/min for isoxsuprine. Glucocorticoid therapy used to accelerate fetal lung maturation[17] was 12 mg betamethasone given intramuscularly and repeated once at 12 hours; two additional injection courses

were given every 7 to 10 days, up to 34 weeks' gestation.

A final, complete data sheet was then generated for each case and reviewed by one of the authors (R.K.L.). All missing and obviously incorrect data were identified and corrected when possible. Statistical analysis was carried out in two stages. For the first stage, the χ^2 test (not continuity corrected) with Goodman pairwise comparisons or single-factor analyses of variance with pairwise comparisons (Bonferroni) was used; for the second stage, two-factor analyses of variance (simultaneous model/regression approach) or log-linear models for contingency tables with tests of partial association were used. Some first-stage analyses were redone with the addition of a covariate, by use of logistic regression or analysis of covariance.

Results

Three hundred thirty-one infants (263 singletons and 68 twins) delivered of 297 mothers from Jan. 1, 1976, through Dec. 31, 1983, were identified for inclusion in the study. The mothers of 130 infants (39.3%) received no tocolysis, 33 (10.0%) received only isoxsuprine, 70 (21.1%) only ritodrine, 43 (13.0%) only terbutaline; and 55 (16.6%) received either a combination of the above tocolytic agents or another agent such as ethyl alcohol, magnesium sulfate, or indomethacin. As shown in Table IV, there was a substantial change in the use of tocolytics over time. While this is explained in part by the lack of availability of ritodrine and terbutaline in the earlier years, treatment versus no treatment also varied from a no-treatment high of 47.1% in 1976 to 1977 to a low of 32.3% in 1980 to 1981 among these low-birth-weight babies ($p = 0.199$ for comparison of no-treatment rates over 2-year time periods).

The duration of tocolytic treatment averaged 2.3 days and ranged from 12 hours to 98 days. The interval between discontinuation of tocolysis and delivery was ≤24 hours in 91% of babies and <4 hours in 69%. Significant maternal side effects were uncommon but did include two cases of pulmonary edema and one of arrhythmia. Tocolysis was discontinued or the agent changed in 10% of cases to lessen side effects such as tachycardia, anxiety, and nausea.

Two hundred seventeen (66%) infants had been exposed in utero to two or more doses of corticosteroids. The mean gestational age at delivery for all infants was 28.6 weeks (range, 21 to 34 weeks); the mean birth weight was 1060 gm (range, 320 to 1495 gm). The outcome distribution for the 331 infants is shown in Fig. 1. The causes of the 15 late deaths (1 to 36 months after discharge) were sudden infant death syndrome ($n = 3$); heart disease ($n = 2$), pulmonary failure ($n = 2$), drowning ($n = 2$), acquired immunodeficiency syndrome ($n = 1$), meningitis ($n = 1$), gastroenteritis ($n = 1$), and unknown ($n = 3$). Of the 239 infants who left the hospital alive, 177 have been evaluated at least once during the first year of life, 101 were seen at 3 years of age, and 58 at age 4.

To examine various kinds of outcomes in relation to the use or nonuse of specific β-sympathomimetic agents, we excluded 55 babies who were exposed either to combinations of β-sympathomimetic agents or to other tocolytic therapies, leaving data on 276 babies for analysis. Of these, 130 had received no tocolytic agent, 43 received terbutaline, 70 ritodrine, and 33 isoxsuprine.

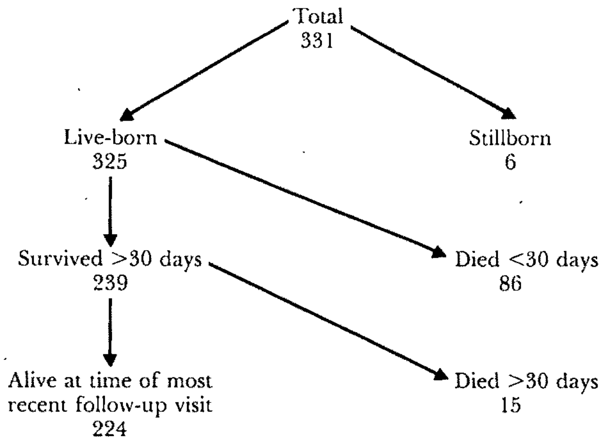

Fig. 1. Outcome of 331 infants with birth weights ≤1500 gm.

In our first-stage analyses, various maternal antepartum and intrapartum variables were compared by type of β-sympathomimetic treatment (none, isoxsuprine only, ritodrine only, terbutaline only) while time period was ignored; no significant differences were found. However, some of the neonatal and pediatric variables analyzed did show significant overall differences with respect to these treatments: trauma (Table V), mortality (Table VI), birth weight (Table VII), highest indirect bilirubin concentration (Table VIII), average caloric intake during the first week of life (Table IX), and maximal peak inspiratory pressure used during assisted ventilation for RDS (Table X). The incidence rates of RDS, patent ductus arteriosus, and intraventricular hemorrhage did not exhibit significant overall differences due to type of β-sympathomimetic treatment, and these results are not shown.

Significant pairwise comparisons between treatments (Bonferroni adjusted multiple comparisons with family significance level ≤0.05) were present for the following: trauma (Table V), terbutaline greater than ritodrine; mortality (Table VI), none greater than terbutaline; maximum peak inspiratory pressure (Table X), none greater than terbutaline; maximum indirect bilirubin (Table VIII), none greater than ritodrine, isoxsuprine greater than ritodrine and terbutaline; caloric intake (Table IX), isoxsuprine greater than none and ritodrine. A greater than B signifies that the mean or incidence for treatment A was greater than for treatment B. There were no significant pairwise comparisons for birth weight, RDS, patent ductus arteriosus, or intraventricular hemorrhage.

Although differences among treatments in overall means of gestational age were not statistically significant in this study ($p = 0.3836$), such differences could have substantial effects on some other neonatal outcomes. Therefore the nine variables just discussed were reanalyzed for overall differences among treatments with linear adjustment for gestational age. Birth weight was found to exhibit overall differences between treatments more significantly ($p = 0.0027$) with this adjustment, and a significant pairwise comparison was found: Ritodrine greater than none. For the other eight variables, adjustment produced either the same or fewer significant pairwise comparisons.

It is important to consider how many of the 66 variables analyzed might have shown significant overall differences among treatments as a result of chance alone. At the 0.05 level, six tests were found to be significant, whereas 3.3 would be expected as a result of chance alone. Five of these six were also significant at the 0.025 level, whereas only 1.65 would be expected. It is likely then that some, but not all, of these significant findings represent real differences.

Because the choice of tocolytic agents changed dramatically over time, it was important to examine the apparent differential effects of the different β-sympathomimetic agents for possible confounding by effects related to time period. To do this, subsets of the data were examined in which a single β-sympathomimetic agent had been received by at least five babies in each of at least two time periods. Within the following subsets, the indicated β-sympathomimetic agent could be compared with no treatment over the same time periods: terbutaline, 1978 to 1979 versus 1980 to 1981; ritodrine, 1980 to 1981 versus 1982 to 1983; isoxsuprine, 1976 to 1977 versus 1978 to 1979. Two kinds of time-related effects were examined: time period effects on the average over treatments (main effects of time period), and treatment-by-time-period interaction effects. If the significant time-related effects occurred with no more than chance frequency, this would suggest (but not prove) that time period reasonably could be ignored in comparing the different treatments.

Results of these analyses are summarized in the tables of means or incidence rates (Tables V to X), not including those for RDS, patent ductus arteriosus, or intraventricular hemorrhage. There were three significant tests for treatment main effect that were not invalidated by significant time-related effects: Trauma (Table V) was observed significantly more frequently in infants exposed to terbutaline than in those whose mothers were untreated ($p = 0.017$). The mortality rate was significantly higher for the untreated group as compared with infants exposed to terbutaline ($p = 0.022$) and ritodrine ($p = 0.046$) (Table VI). Finally, maximum peak inspiratory pressure when RDS is present (Table X) was significantly lower in infants exposed to terbutaline than in the untreated ($p = 0.021$).

*Incidence of perinatal deaths, when $n \geq 5$ (n is number of cases with nonmissing values on this variable).

†Significant results from first-stage analyses ($p < 0.05$): overall comparison between treatments, $p < 0.0157$; pairwise comparisons, none greater than terbutaline. Significant results from subset analysis ($p < 0.05$): terbutaline versus none, 1978 to 1979 versus 1980 to 1981, treatment main effect, $p = 0.021$; none greater than terbutaline; ritodrine versus none, 1980 to 1981 versus 1982 to 1983, treatment main effect, $p = 0.046$; none greater than ritodrine; treatment-by-time-period interaction effect, $p = 0.043$.

Among the 48 tests of time-related effects, seven tests were significant at $p < 0.05$, whereas only 2.4 would be expected by chance. Thus most of the evidence suggesting confounding of overall treatment differences with time period effects is probably real.

Finally, when the data gathered in the longitudinal follow-up examinations were examined, no differences were found when infants of untreated mothers were compared with those exposed to the various tocolytic agents.

In summary, there were apparently real treatment differences for the short-term variables mortality and maximum peak inspiratory pressure when RDS was present. Evidence of treatment differences for trauma was somewhat inconsistent among analyses but suggested a higher incidence for terbutaline than for no treatment or ritodrine. When the various components of the trauma variable were dichotomized as present or absent, only the presence of bruising continued to show statistical significance. Conversely, there was no evidence of treatment effect or confounding for intraventricular hemorrhage. The evidence of differences among treatment groups for highest indirect bilirubin, caloric intake in the first week of life, and birth weight appears to be somewhat confounded by time period effects. Similarly, the evidence of no treatment effect for patent ductus arteriosus and RDS may be somewhat confounded.

Comment

The purpose of this study was to examine the possibility of short-term or long-term effects of various β-sympathomimetic agents on premature infants weighing ≤1500 gm. As the study design was observational, differences among treatment groups may suggest treatment effects, but effects of subject selection and uncontrolled confounding also are possible. Maternal side effects were too infrequent to allow meaningful comparison of agents on those outcomes.

The decision to use β-sympathomimetic agents for tocolysis was made on clinical grounds for individual patients by the obstetric staff; the agents were not used

in these patients under a protocol for a prospective clinical trial. Thus the evaluation of the outcome of the infants was based on a retrospective review of our neonatal and follow-up data.

It may be asked why the different β-sympathomimetic agents were considered separately in these analyses, rather than being compared collectively with no treatment. Because different degrees of β-adrenergic receptor selectivity have been demonstrated for the agents, we thought it prudent to consider possible clinical effects of such differences.

Of the major neonatal outcome variables, only mortality showed a significant difference, with the group receiving terbutaline or ritodrine having a lower mortality rate than the untreated group. The cause for this lessened mortality is not apparent but may be related to the higher birth weights in the β-sympathomimetic group, although the average difference in birth weight between the two groups was small (83 gm). Because this was not a controlled trial, the differences in mortality rates should be interpreted with caution.

Fifteen deaths occurred after the neonatal period; there is no evidence to indicate that these were caused by the maternal β-sympathomimetic treatment. The occurrences of three cases of sudden infant death syndrome in this group is similar to the incidence that has previously been reported among infants of low birth weight.[18]

β-Sympathomimetic agents are known to have marked effects on the fetal lung in experimental animals. These effects include release of pulmonary surfactant,[19-21] decreased lung liquid production,[21, 22] resorption of alveolar fluid,[22] and a decrease in lung water content[19, 23]; all of these actions might be expected to decrease RDS. Conversely, treatment with β-sympathomimetic agents also has been reported to deplete surfactant stores,[24] an effect that might increase the incidence of RDS. In any case we found no difference in incidence of RDS between the infants receiving any one of the β-sympathomimetics and those receiving none. There are at least two possible explanations: (1) The effects of β-sympathomimetics are less pronounced in human fetuses than in laboratory animals; (2) an effect similar to that of β-sympathomimetics may

*Mean maximum peak inspiratory pressure requirement (cm H_2O), when $n \geq 5$ (n is number of cases with nonmissing values on this variable).

†Significant results from first-stage analyses ($p < 0.05$): overall comparison between treatments, $p < 0.0194$; pairwise comparisons, none greater than terbutaline. Significant results from subset analysis ($p < 0.05$): terbutaline versus none, 1978 to 1979 versus 1980 to 1981, treatment main effect, $p = 0.021$; none greater than terbutaline.

occur in the process of labor. Of interest was the finding that maximal peak inspiratory pressure was significantly lower in infants with RDS in the terbutaline group than in the no-treatment group, suggesting that the lung disease was milder. It was also lower in the ritodrine-treated group but not significantly so.

The lowest caloric intake during the first week of life was in the untreated group. This may have been because they were more unstable and less tolerant of fluids and enteric feedings. Although there were statistically significant differences in the maximal concentration of indirect bilirubin, the actual differences were small and were not clinically important.

Of the 37 cases found to have some form of trauma, all but six had bruising. These six consisted of minor lacerations ($n = 1$), forceps marks ($n = 4$), and abrasions ($n = 1$). There were no cases of nerve injury or fracture. We see no clear explanation of the apparent excess of these minor traumas in infants exposed to terbutaline.

Samples sizes for comparisons between types of β-sympathomimetic treatments on long-term follow-up assessment variables (Tables I and II) were modest at best. Anthropometric measurements (head circumference, height, weight) were made on 100 to 120 subjects at age 3 and 21 months but only on smaller numbers at other ages. Intelligence quotient was measured in 130 subjects at age 1 year, in 117 at age 2, and in smaller numbers of older children. In the comparisons involving sample sizes of ≥100, about 50 subjects had received no β-sympathomimetic agents, 25 to 35 had received ritodrine, 20 to 30 had received terbutaline, and 10 had received isoxsuprine. Therefore only rather gross differences between treatments in long-term outcome could have been detected as statistically significant.

Our experience suggests that the use of β-sympathomimetic agents for tocolysis does not have any substantial, statistically significant adverse effects on the neonatal course of infants whose birth weights were ≤1500 gm. While statistically significant adverse effects were not found in the longer-term outcomes, these comparisons are very insensitive, particularly after the first year of life, because of marked reductions in the number of subjects for whom results were obtained. The lower mortality rate in the β-sympathomimetic group should not be directly attributed to the use of β-sympathomimetic agents.

Discussion

DR. DURLIN HICKOCK, Seattle, Washington. Dr. Laros has presented an important article describing both the short- and long-term effects of β-sympathomimetics on the infant exposed in utero. In this cohort of infants born at the University of California, San Francisco, 210 infants exposed to one or more β-sympathomimetic drugs were compared with 130 infants of similar birth weights whose mothers did not receive β-sympathomimetic drugs. Few differences were found in the long-term variables examined. The only consistent short-term differences between the treated and untreated groups appeared to be a reduction of perinatal mortality in infants whose mothers were treated with ritodrine or terbutaline and a lower peak inspiratory pressure when RDS was present.

In metaanalyses of placebo-controlled, randomized trials, the β-sympathomimetics are highly effective for prolonging delivery >48 hours, although to a lesser extent preventing birth before the thirty-seventh completed week. No significant effect on reduction of perinatal death has been demonstrated to date. Furthermore, from experimental studies there appears to be no influence on the risk of RDS.[1]

All of the β-sympathomimetics cross the placenta, although the ratio of fetal-to-maternal serum levels varies with the different drugs. Fetal effects, for the most part, parallel closely those observed in the mother. After β-sympathomimetic infusion, predictable increases in glucose, lactate, and insulin occur, with a return to baseline levels within 72 hours, with the exception of lactate, which remains elevated. Neonatal hypoglycemia, hypocalcemia, ileus, and hypotension have been reported to be more common in infants whose mothers were treated with isoxsuprine and who were delivered within 48 hours of treatment.[2]

Much less is known regarding potential long-term effects on the fetus from maternal β-sympathomimetic therapy. Only 18 placebo-controlled trials involving <500 women allocated to β-sympathomimetic treatment have been reported, and few of these studies involved infant follow-up beyond the initial hospital stay. Reports to date, however, have been reassuring with lack of significant long-term effects reported by Polowczyk et al.[3] in 20 children and by Dr. Laros in the current study.

Dr. Laros is to be congratulated in presenting an important study. All too often the obstetric literature concentrates on studies of clinical efficacy of a therapy or intervention for pregnancy disorders and loses sight of the important issue of clinical safety. The effectiveness of treatment is often much easier to measure, less costly to study, and more exciting in its presentation. Clinical safety, nonetheless, remains as important as clinical efficacy in the evaluation of new treatments and technologies. We have already experienced the unfortunate example of the excess risk of vaginal adenocarcinoma caused by in utero exposure of diethylstilbestrol.

Any comments I have to Dr. Laros should be considered as potential limitations rather than criticisms. In a nonexperimental study such as this, many of the determinants of the outcomes of interest cannot be adequately controlled for, thus limiting the generalizability of the results. The lack of serious adverse effects in this study, however, remains an important finding. I have several questions for Dr. Laros, mainly centering around the issue of those who were untreated: Were these patients too advanced in labor to be treated? What proportion of the nontreated group were deemed not to be candidates for therapy because of rupture of membranes?

Dr. Robert C. Goodlin, Denver, Colorado. This is a much-needed study. I have just two questions. Have you looked at the incidence of fetal growth retardation among these prematurely born babies? It might make a great difference in outcome. In Europe, terbutaline is considered effective therapy for prevention of hyaline membrane disease,[1] just as we think steroids are effective. Do you agree that it is?

1. Bergman B, Hedner T. Antepartum administration of terbutaline and the incidence of hyaline membrane disease in preterm infants. Acta Obstet Gynecol Scand 1978;57:217-21.

Dr. Richard N. Bolton, Portland, Oregon. "Bruising," like beauty, is in the eye of the beholder. There are three groups, each divided into 2 years—isoxsuprine, terbutaline, and ritodrine. Could there have been an observer during the terbutaline years, not present during the isoxsuprine or ritodrine years, who, because of personal sensitivity, saw and recorded more "bruising"?

Dr. Thomas Garite, Orange, California. The safety of therapy is a very important issue. Long-term follow-up is obviously missing in these patients. In comparing a group that received no tocolytic agents with a group who received these agents, the difference in outcome seen might be explained either by differences in the agents or by other differences between the two groups. When the patient is not a candidate for tocolysis or when the drug is contraindicated, she is more likely to have a problem that predisposes the baby to birth asphyxia and neonatal complications. Examples are chorioamnionitis, abruptio placentae, and premature rupture of membranes, the latter predisposing to umbilical cord compression. Dr. Laros, was any effort made to see whether the condition at birth might have explained any differences in perinatal mortality, Apgar scores, umbilical cord blood gases, or other outcome?

Dr. Laros (Closing). Dr. Hickok, you are absolutely correct. There was a difference in the *none* group. The vast majority of patients in this group, on the order of 80%, were not considered candidates for tocolysis because of relatively far advanced cervical dilation when they were first seen in our unit. Approximately 10% of the *none* group had premature rupture of membranes, and in about 5% or 10%, lack of treatment was apparently just a matter of choice by the attending physician.

Dr. Goodlin and Dr. Hickok, there are two clear studies, one from Germany and one recent one from the United States, pointing out that, despite the wide use of β-sympathomimetics and other tocolytic agents, there has been no decrease in the incidence of preterm delivery. We have to continue to ask ourselves exactly what are we doing.

Dr. Garite, we did look quite carefully at confounding factors that might have an effect on outcome. There was no difference in the incidence of chorioamnionitis in the four treatment groups. We did have cord blood gases and Apgar scores on virtually all of these babies, and there were no differences among the groups. One is always in the position of back filling when one tries to convince the reader that the various groups in an observation study are equal. We are as comfortable as we can be from an epidemiologic viewpoint that these were comparable groups and that the differences observed or not observed are due to treatment and not to ascertainment bias.

Dr. Goodlin, the incidence of intrauterine growth retardation was not different in the various groups.

Dr. Bolton, I also have been suspicious that the eye of the beholder is an important issue. Unfortunately, we could not explain away the *trauma* issue because our second level of analysis took into account time, which should control for different observers.

Ten-year follow-up of patients with secondary amenorrhea and normal prolactin

Val Davajan, MD,[a] Oscar Kletzky, MD,[b] Michael Vermesh, MD,[a] and Debra J. Anderson, MD[a]
Los Angeles and Torrance, California

A group of 46 patients with secondary amenorrhea without galactorrhea or hyperprolactinemia were studied retrospectively after being clinically categorized into four groups with the use of progesterone-induced uterine bleeding and measurement of serum gonadotropins and prolactin levels. The ability to have regular spontaneous menstrual cycles and to conceive was assessed after a follow-up period of 10 years. Patients who had been classified as having hypothalamic pituitary "failure" (hypoestrogenic amenorrhea) with low levels of circulating estradiol had a greater rate of recovery of spontaneous ovulation and menses when compared with patients who had been classified as having only hypothalamic pituitary dysfunction (euestrogenic amenorrhea). The patients with diagnosis of hyperandrogenic chronic anovulation or polycystic ovary syndrome generally required clomiphene citrate for induction of ovulation and almost all the patients with premature ovarian failure (hypergonadotropic amenorrhea) remained estrogen-deficient and unable to ovulate. Hyperprolactinemia or an identifiable pituitary adenoma has not developed in any of the patients to date. (AM J OBSTET GYNECOL 1991;164:1666-72.)

Key words: Secondary amenorrhea, hyperprolactinemia, euestrogenic secondary amenorrhea, hypoestrogenic secondary amenorrhea, hypergonadotropic secondary amenorrhea

Patients with secondary amenorrhea and normal serum prolactin (PRL) levels can be clinically categorized into four groups with the use of progesterone or progestin-induced uterine bleeding and measurement of a single serum gonadotropin level.[1] Those with uterine bleeding after administration of progesterone were reported to have serum estradiol levels >40 pg/ml (euestrogenic amenorrhea) and were further subdivided into two groups on the basis of serum luteinizing hormone (LH) levels. Elevated serum LH levels ≥25 mIU/ml or an LH/follicle-stimulating hormone (FSH) ratio greater than three are seen in patients with polycystic ovary syndrome, also referred to as hyperandrogenic chronic anovulation.[2] Hypothalamic dysfunction was diagnosed in patients with normal serum LH levels. Patients with no uterine bleeding to progesterone challenge (<40 pg/ml of estradiol, hypoestrogenic amenorrhea) were further subdivided into group of those with hypothalamic pituitary failure if the serum FSH level was low or low-normal and those with premature ovarian failure (hypergonadotropic hypogonadism) if the serum FSH level was noted to be elevated into the menopausal range.

This 10-year retrospective study analyzed the reproductive changes that occurred in 46 women with secondary amenorrhea and normal serum (PRL) levels, specifically to the prevalence of establishment of spontaneous normal menses and ability to conceive.

Material and methods

A group of 46 patients with secondary amenorrhea without galactorrhea or hyperprolactinemia were studied retrospectively. At the initial visit between 1974 and 1977, these patients had undergone 6 to 48 months of amenorrhea. Their ages ranged between 18 to 34 years (Table I). Eighteen (39%) patients had normal menses and 28 (61%) had oligomenorrhea before onset of amenorrhea. In addition to those with hyperprolactinemia, patients with hypothyroidism or diabetes mellitus were excluded from the study. Each patient on initial presentation had a complete medical history and physical examination that included a pelvic examination, a thorough breast examination to exclude galactorrhea, and appropriate routine laboratory tests. The possible confounding factors for each group of patients are listed in Table II. An intramuscular injection of 100 mg of progesterone in oil or medroxyprogesterone acetate (Provera) 30 mg orally for 3 days was given to all 46 patients. Those who responded with uterine bleeding 2 to 14 days after the administration of progesterone (positive response) had a serum LH level deter-

mined. If hirsutism, obesity, or acne was also present in this group of patients serum FSH, dehydroepiandrosterone (DHEA) sulfate and total serum testosterone levels were also measured. The initial four patients in the series were seen before serum DHEA-sulfate levels were available and therefore had 24-hour urinary 17-ketosteroid values determined. Routine diagnostic laparoscopy or ultrasonography were not used in this study to confirm the diagnosis of polycystic ovary syndrome or hyperandrogenic chronic anovulation.

Patients who did not respond with uterine bleeding after administration of progesterone (negative response) had serum FSH level measured. Only hypoestrogenic patients with low or normal serum FSH levels (<10 μIU/ml) had hypocycloidal polytomograms ($n = 5$) or computed tomography (CT) scans ($n = 4$) of the sella turcica. These initial studies were done before use of magnetic resonance imaging.

Serum LH, FSH, TSH, PRL, testosterone, and DHEA- sulfate were determined by previously reported radioimmunoassay methods.[3] Significance of differences between initial hormone values and those obtained 10 years later in the same patients were obtained with the use of the paired Student *t* test. Results are reported as mean ± SEM.

Results

There were 30 patients with a positive uterine bleeding response to progesterone and 16 with a negative response. Any amount of bleeding was considered positive. Of the 30 patients with positive response, the diagnosis polycystic ovary syndrome (hyperandrogenic chronic anovulation) was made in 13 patients because they had either an elevated serum LH level of ≥25 mIU/ml ($n = 8$)[4] or an LH/FSH ratio ≥3 ($n = 5$). In addition, all 13 patients had one or more physical signs of hyperandrogenism such as obesity, hirsutism, and acne. In this group the mean serum testosterone level was 104.5 ± 4.85 ng/dl (normal, 20 to 85 ng/dl), mean DHEA sulfate was 3.26 ± 0.19 (normal, 0.5 to 2.8 μg/ml) (Fig. 1). Intermittently all 13 patients were treated with cyclic oral contraceptives; only one patient was treated with dexamethasone 0.25 mg daily orally at bedtime, and four with significant acne were treated with spironolactone (100 mg orally daily). Nine of these patients desired pregnancy and were treated with clomiphene citrate. None of the 13 patients spontaneously began to have regular menstrual cycles in the 10 years of follow-up, but after periodic discontinuation of oral contraceptives (from 1 to 6 months) all continued to have withdrawal uterine bleeding in response to progesterone administration. There was either no progression in the hirsutism ($n = 5$) or there was improvement in both the hirsutism ($n = 8$) and acne ($n = 6$) while being treated. After 10 years, the mean serum testosterone level of this group decreased to 70.2 ± 5.1 ng/dl ($p \leq 0.005$) and the DHEA sulfate level decreased to 2.3 ± 0.14 μg/ml ($p \leq 0.005$) (Fig. 1). During the same time period nine patients increased in body weight and as a group body weight increased from 156 ± 5.0 pounds (70.5 kg) to 177 ± 8.2 pounds (80.5 kg) ($p < 0.05$). Four of the nine patients who desired conception achieved at least one pregnancy with clomiphene citrate.

The remaining 17 of the 30 patients with positive response had a normal initial serum LH level of 10.5 ± 0.75 (normal values, 4 to 20 mIU/ml) and 10 years later it was 12.4 ± 1.0 mIU/ml (Fig. 2). Euestro-

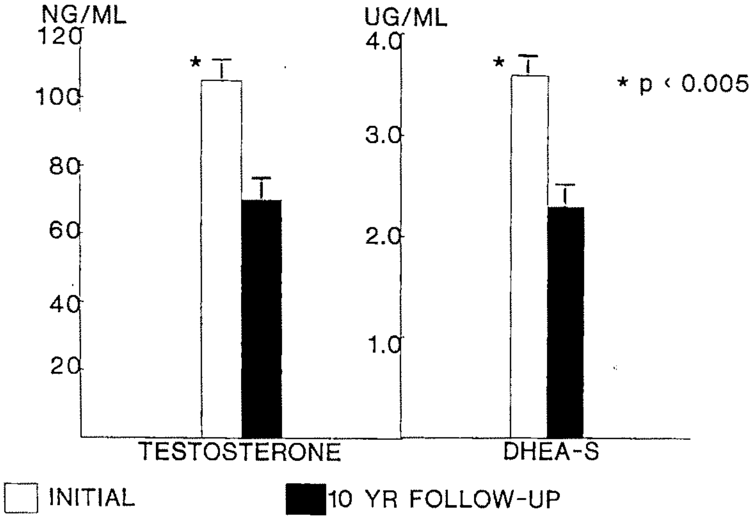

Fig. 1. Secondary amenorrhea: polycystic ovary syndrome serum androgens. Results of serum androgens in initial and 10-year follow-up in the patient with polycystic ovary syndrome (hyperandrogenic chronic anovulation).

genic secondary amenorrhea as a result of hypothalamic dysfunction was diagnosed in these patients. Before onset of amenorrhea three had lost at least 15% of their body weight, two reported to be engaged in excessive physical exercise.[5-7] In six the amenorrhea followed the discontinuation of oral contraceptives.[8] All 17 patients were treated with oral progestin (5 to 10 mg daily) for 10 to 12 days every 60 days and clomiphene citrate was used to induce ovulation in the 12 who wished to conceive. For patients who desired contraception the use of vaginal diaphragm or condoms was recommended.

After 10-year follow-up, all 17 patients discontinued all medications for 1 to 6 months before reevaluation. Serum PRL values remained in the normal range (6 to 20 ng/ml) (Fig. 3) in all but one patient who was taking a psychotrophic drug. The initial mean value was 9.5 ± 0.84 and 10 years later it was 12.8 ± 1.41 ng/ml (± SEM, not significant). During follow-up, three patients resumed spontaneous ovulatory cycles as demonstrated by biphasic basal body temperature and serum progesterone level of ≥8 ng/ml. Oligomenorrhea developed in four patients and 10 continued to have secondary amenorrhea with positive response to progesterone. Six of the 12 patients treated with clomiphene citrate conceived and had at least one successful term delivery. An additional patient conceived spontaneously.

Of the 16 patients with negative response after progesterone administration, nine (aged 19 to 28 years) had a mean serum FSH level of 3.8 ± 0.62 mIU/ml (normal, 2.8 to 9 mIU/ml) and seven (aged 22 to 33 years) had a level of 99.9 ± 8.2 mIU/ml. Hypoestrogenic amenorrhea or hypothalamic pituitary failure was diagnosed in patients with low or low-normal serum FSH levels. Six of nine patients had regular cycles before the sudden onset of amenorrhea. All six had either ≥20% loss of body weight ($n = 5$) or performed excessive physical activity ($n = 1$). The remaining three patients had no known confounding factor. Hypocycloidal polytomography or computed tomography scan studies of the sella turcica did not show any evidence of pituitary adenoma in patients with hypothalamic pituitary failure. Serum cortisol, growth hormone, and PRL response was normal after insulin-induced hypoglycemia,[9] and stimulation with gonadotropin releasing-hormone induced a normal serum LH and FSH response in all patients.[4] These patients were initially treated with replacement oral estrogen/progestin therapy (conjugated estrogen, 0.625 mg orally daily for 25 days and medroxyprogesterone acetate, 5 to 10 mg daily for 12 days). The duration of treatment was variable. During follow-up, six patients recovered spontaneous ovulatory menstrual cycles. Mean serum FSH levels were normal initially (3.8 ± 0.62) and after 10 year follow-up (5.5 ± 0.42 mIU/ml). Mean serum PRL values (10.4 ± 1.17) did not change significantly after 10 years (15.8 ± 5.2 ng/ml) (Fig. 3). Six of these nine patients recovered normal spontaneous menstrual cycles. Three patients remained amenorrheic; however, two of these patients were euestrogenic and began to bleed in response to progesterone and therefore hypothalamic dysfunction was diagnosed. Only one patient remained with the diagnosis of hypothalamic pituitary failure and subsequently had normal results of a magnetic resonance imaging study of the pituitary. All six patients who wanted to conceive did so either spontaneously or after treatment with clomiphene citrate.

Premature ovarian failure or hypergonadotropic

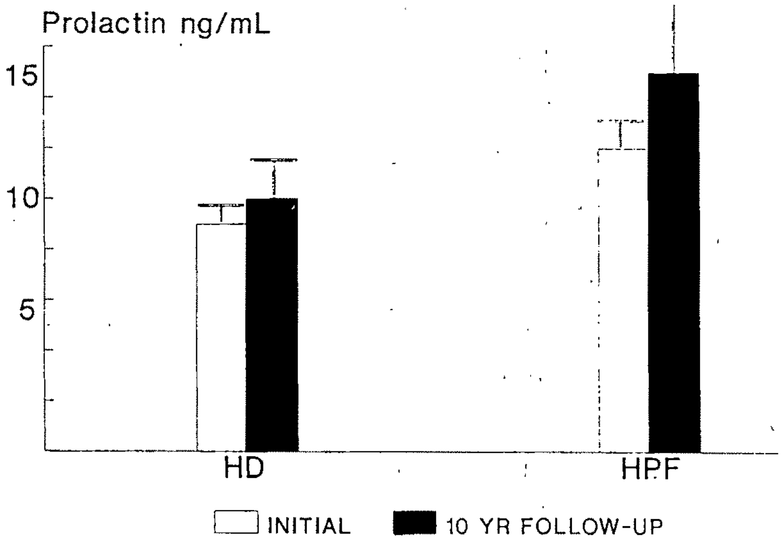

Fig. 3. Secondary amenorrhea: PRL. Serum PRL levels (initial and 10-year follow-up) in patients with hypothalamic dysfunction (euestrogenic amenorrhea) and hypothalamic failure (hypoestrogenic amenorrhea).

amenorrhea was diagnosed in the remaining seven patients with a negative response to progesterone. Five women had an acute onset of amenorrhea. Mean serum FSH level initially was 99.9 ± 8.2 and 10 years later it was 140.4 ± 9.2 mIU/ml ($p \leq 0.05$) (Fig. 2). Antithyroid and antimicrosomal antibody test results were negative in all patients.[10] The three patients younger than 25 years had normal 46,XX karyotype. In the 10-year follow-up two patients had spontaneous but sporadic uterine bleeding episodes. One of the two had a 6-month interval of monthly menstrual bleeding during the sixth year of follow-up. Serum FSH value was 18 mIU/ml during the fourth month of this "recovery" period. All patients had been treated with estrogen-progestin replacement therapy and discontinued all medications for at least 1 month before reevaluation. None of the seven patients conceived although four were treated with high doses of oral estrogen in an effort to trigger ovulation by the "rebound" phenomena.[11]

Comment

The results of this study indicate that patients with hypoestrogenic secondary amenorrhea as a result of low gonadotropin values as a consequence of weight loss and strenuous exercise have a good prognosis as to recovery of normal menstrual cycles (66%). In addition, only three of 17 patients with euestrogenic amenorrhea as a result of hypothalamic dysfunction were having normal menstrual cycles at the end of 10 years (17.6%). Amenorrhea developed in two of these three patients after discontinuation of the oral contraceptives and one was a result of weight loss. In contrast, no patient with hyperandrogenic amenorrhea, polycystic ovary syndrome, or premature ovarian failure recovered spontaneous ovulatory menstrual cycles even after 10 years of follow-up. It has been suggested that patients with hypothalamic euestrogenic amenorrhea have a hypothalamic derangement, whereas patients with hypoestrogenic amenorrhea have either a more profound gonadotropin-releasing hormone deficiency or an intrinsic pituitary alteration.[12] It was therefore assumed that these patients would not resume a spontaneous menstrual cycle. The results of this study did not bear this out. As stated earlier, only three of 17 (18%) patients with euestrogenic amenorrhea (hypothalamic dysfunction) were having spontaneous normal menstrual cycle as compared with six of nine patients with hypoestrogenic amenorrhea (hypothalamic pituitary failure) (67%). Analysis of these patients' abilities to conceive revealed that 17 of 27 (63%) patients with the collective diagnoses of hyperandrogenic, euestrogenic, and hypoestrogenic amenorrhea who wished to conceive were able to do so either spontaneously or after treatment with clomiphene citrate. In contrast, no patient with premature ovarian failure was able to conceive. In this study human menopausal gonadotropin therapy was not used to induce ovulation in patients who did not conceive with the use of clomiphene citrate. During the majority of the time that this study was undertaken, human menopausal gonadotropin therapy was not being used to induce ovulation except in patients with hypoestrogenic amenorrhea. Because all the patients in this group who desired to conceive ovulated spontaneously or responded to clomiphene, human menopausal gonadotropin therapy was not used in this study. This is in marked contrast with what is offered to patients today. Even women who ovulate spontaneously and do not conceive are treated with human menopausal gonadotropin.

In patients with hyperandrogenic amenorrhea, the hirsutism was either improved with regard to its courseness and retarded with regard to its speed of regrowth ($n = 8$) or remained unchanged ($n = 5$). None of the patients had worsening of hirsutism. All patients reported overall improvement in skin condition. All these patients showed improvement in androgen levels on therapy. It should be noted that the hirsutism was not completely eradicated and therefore appears to be permanent once it is present. The most chronic complaint encountered in following up the 13 patients with hyperandrogenic amenorrhea was the difficulty in weight control. Although all four groups of patients gained weight in the 10-year follow-up, the patients with hyperandrogenic amenorrhea were heavy to begin with and continued to gain weight.

It should be noted that hyperprolactinemia did not develop in any of the patients with hypothalamic dysfunction or hypothalamic pituitary failure in the 10-year follow-up. In conclusion, this longitudinal study, although relatively small in number of patients, provides guidelines for counseling patients with amenorrhea as to prognosis for spontaneous recovery of menses and chance of conception.

Discussion

DR. TAWFIK H. RIZKALLAH, Phoenix, Arizona. Dr. Davajan classified 46 normoprolactinemic patients with secondary amenorrhea into four categories. This classification was dependent on the patient's response to administered progesterone or progestational agent, androgenic state, serum estradiol, and FSH levels. With this in mind, Dr. Davajan retrospectively analyzed the reproductive outcome of patients in each category.

The objective of Dr. Davajan's study was to map out a guideline for counseling patients with similar problems as to their reproductive abilities.

In a 10-year follow-up, none of the patients in the group with polycystic ovary syndrome returned to normalcy and unfortunately some showed a significant increase in body weight, which may have contributed adversely to their medical problems.[1]

In the group with premature ovary failure, replacement therapy with estrogen and progestational compounds is essential. Fertility in this group may be better achieved by ovum donation and embryo transplantation rather than by any heroic attempts at induction of ovulation with high doses of gonadotropin. Spontaneous ovulation, although infrequent, was seen to occur in about 20% of patients studied, and spontaneous pregnancy has occurred while patients received exogenous estrogen therapy.[2]

In the groups with hypothalamic dysfunction and hypothalamic pituitary failure, weight loss and excess physical exercise in eight patients are contributary factors that led to amenorrhea; one patient had anorexia nervosa. Previously published data[3] showed that excess physical activity was responsible in the delay of menarche, irregular cycles, or secondary amenorrhea.

The adverse effect of stress and the beneficial effect of physical rest on the function of the hypothalamic pituitary ovarian axis is well documented. Stressed athletes (runners) were observed to have amenorrhea more frequently than nonstressed ones.[4] Top performer-athletes who participate in sports that require tremendous physical activity and endurance were reported to have a higher incidence of amenorrhea and stress.[5] The role of stress has to be considered when evaluating patients with hypothalamic amenorrhea. An increase in the production of cortisol was seen in patients with hypothalamic amenorrhea when compared with normal controls.[6] In vivo, the administration of corticotropin-releasing hormone resulted in inhibition of LH and FSH secretion.[7] Also, intracerebroventricular administration of corticotropin-releasing hormone was found to reproduce many of the components of the symptom complex of measured depression, hypercortisolism, hypothalamic hypogonadism, anorexia, and anxiety.[8] Physical rest in a group of amenorrheic athletes appeared to lead to resumption of menses without any increase in body weight.[9] Recent studies showed an aberrant pattern of LH pulsation in amenorrheic and cyclic athletes when compared with cyclic sedentary women.[10] In weight loss–related amenorrhea in nonathletes, the pulsatile pattern of LH secretion showed an increased frequency, reduced amplitude, and short duration.[11] Other investigators showed that these patients exhibited abnormal thermoregulation when exposed to low or high external temperatures. Also, partial diabetes insipidus was detected in about one fourth of this group, indicating some form of hypothalamic dysfunction.[12]

In anorexia nervosa the production of corticol was shown to be elevated beyond the normal control group. Recovery from anorexia nervosa was accompanied by about a 30% decrease of the production rate of cortisol.[13] Moreover, adrenocorticotropic hormone–induced adrenal androgen production was found to be impaired at low body weight and that return to normal response occurred after a long-term weight recovery.[14]

The element of depression in anorexia nervosa is another variable to be considered. Measurement of corticotropin-releasing hormone in cerebrospinal fluid in underweight patients and also at intervals after weight restoration, showed elevated levels of corticotropin-releasing hormone that normalized after weight gain. A significant positive correlation was found between cerebrospinal fluid corticotropin-releasing hormone levels and depression scores in weight-corrected patients.[15] Recently it was shown that endogenous opiates play a role in decreasing LH secretion in women with anorexia nervosa. Naloxone infusion led to an increase in pulsatile release of LH in about one half of the patients studied.[16] Induction of ovulation was achieved with naloxone was given daily for 28 days to three women with hypothalamic amenorrhea but without weight loss.[17]

Hypothalamic amenorrhea is a multifactorial disorder. The precise mechanism is not well understood, but a number of factors may contribute to suppression of gonadotropin-releasing hormone pulse generator that will affect the production of gonadotropins. So far, weight loss, excessive exercise, and stress-related amenorrhea, may lead to aberrant production of corticotropin-releasing hormone, cortisol, and β-endorphins, which have been shown to play a significant role in the modulation of the production of gonadotropins and thus may be a causative factor for amenorrhea.

Attempts to correct the underlying predisposing factor in hypothalamic amenorrhea may be the key to a return to normal hypothalamic pituitary ovarian and hypothalamic pituitary adrenal function.

Dr. Simon R. Henderson, San Francisco, California. Isn't the term *failure* as in hypothalamic-pituitary failure rather a strong term? Because there was such good recovery in that group, shouldn't we perhaps talk about those women as having hypoestrogenic hypothalamic-pituitary dysfunction? How did you treat these patients?

Dr. Kenneth A. Burry, Portland, Oregon. I have chronic battles with my colleagues in medical endocrinology because they like to test everything. Unfortunately for the women in the group with hyperandrogenic chronic anovulation, my tester colleagues have a tendence to want to rule out adult-onset adrenal hyperplasia. How do you approach this problem?

Your experience with suppression of DHEA sulfate in women who take oral contraceptive pills is very similar to our experience with short-term therapy with gonadotropin-releasing hormone analogs. We saw the same reduction in serum levels of this adrenal steroid. What do you think the mechanism might be?

Dr. George Winch, San Francisco, California. This article provides excellent long-term follow-up. I have a patient who had anorexia nervosa diagnosed at age 18 years and had amenorrhea until age 36 years. Having seen her earlier for amenorrhea, I was asked to see her again because of prolonged bleeding. A therapeutic dilatation and curettage revealed endometrial tissue compatible with a well-differentiated endometrial adenocarcinoma. A slide was reviewed by pathologists at the University of California in San Francisco and by Dr. Donald Woodruff of Johns Hopkins University. She was treated with cyclic progestin for 3 months. She has continued to have normal periods for 6 years and repeated curettage procedures about every other year have all revealed normal appearing endometrium. Dr. Davajan, in the small group of patients who started spontaneous cyclic bleeding, did you encounter abnormalities of bleeding? Did you find abnormal endometrium after prolonged periods of unopposed estrogen stimulation?

Dr. Wayne Heine, Tucson, Arizona. This is a very informative article that provides follow-up for 10 years by a single observer. I have two questions (1) In the group with elevated gonadotropin values, did you find an increased incidence of autoimmune problems or other endocrinopathies? (2) Did you test any group for chromosomal abnormalities and if so did you find any?

Dr. Davajan (Closing). Dr. Henderson, I agree that we ought to use terms other than *dysfunction* or *failure* in reference to amenorrhea. I should replace the old terms with *hypoestrogenic* and *euestrogenic amenorrhea.*

All patients in the hypoestrogenic state were treated with estrogen and progestin replacement throughout the entire 10 years unless they wanted to conceive. Six patients regained 22% of their mean body weight and started menstruating when they stopped exercising. The patient with anorexia nervosa underwent psychiatric therapy, regained some of her weight, and achieved a normal cycle.

Dr. Burry, I look for congenital adrenal hyperplasia if the patient's serum DHEA sulfate level is significantly elevated and she has virilization, not just hirsutism and acne. I have been using serum level of 4 μg/ml of DHEA sulfate as my cutoff to look at a 17-hydroxyprogesterone. Although normally I do not diagnose congenital adrenal hyperplasia it is something for which you should be alert. You have to think about the unusual case but the cases in this study were all simple.

Dr. Winch, none of the women who I considered to have made a normal recovery had dysfunctional or abnormal uterine bleeding and biopsy specimens were not obtained. They all had verification of ovulation by serum progesterone and biphasic basal body temperature recordings. I also did not obtain biopsy specimens from patients who had oligomenorrhea, although I recognize that you may get such a patient who shows up with hyperplasia or even early carcinoma. Now that I have the pipelle rather than the Novak curette, I am doing a lot more. I like the pipelle curette because it does not hurt the patient.

Dr. Heine's question about autoimmunity and chromosomes is an excellent one. All seven patients in the hypoestrogenic, hypergonadotropic group were checked for serum antithyroid antibodies and all results were negative. Each of the three patients younger than 25 years had a normal karyotype. At the end of the 10-year study all seven had 24-hour urinary free cortisol looking for early Addison's disease and serum calcium and phosphorus looking for parathyroid involvement. All test results were normal.

Glucose challenge testing in pregnancy

Duncan R. Neilson, Jr., MD, Richard N. Bolton, MD, Robert P. Prins, MD, and Carl Mark III, MD

Portland, Oregon

This study examines results of routine glucose challenge screening in 608 third-trimester patients in a private practice setting. Four patient categories were defined on the basis of the results: normal, abnormal screen with normal glucose tolerance test, borderline glucose tolerance test, and gestational diabetes. When only standard prenatal management practices were used, the fetal outcomes in the four groups were not measurably different. The costs of these procedures resulted in an expenditure of $722.31 per diagnosis of gestational diabetes. This seems excessive in view of the negligible impact of these studies on fetal outcome. Our impression was that routine third-trimester dietary counseling, postprandial glucose monitoring without challenge testing, and evaluation of cases of suspected fetal macrosomia would result in comparable outcome at significantly reduced cost. (AM J OBSTET GYNECOL 1991;164:1673-9.)

Key words: Glucose tolerance, pregnancy, cost-effectiveness, macrosomia

The significance of the diagnosis of gestational diabetes to the pregnant patient and her fetus has been a matter of some concern in our practice. Therefore, in accord with the recommendations of the American Diabetes Association and the American College of Obstetricians and Gynecologists,[1, 2] our office began routine glucose screening of private prenatal patients in 1985.

Before that time we used the established risk guidelines for glucose screening[3]: patients with a history of macrosomia, obesity, intrauterine death, malformations, prior gestational diabetes, glucosuria, or a strong family history of diabetes.

We elected to use the standard 50 gm oral glucose challenge in the nonfasting state with a 1-hour plasma level detected by the glucose oxidase method. We decided to emphasize specificity, at the possible sacrifice of sensitivity, by using a screen level of 150 mg/dl.[2] Those patients with glucose levels ≥150 mg/dl were subjected to a 3-hour oral glucose tolerance test (GTT) after an overnight fast. Actual management of patients was based on postprandial glucose values that were measured in patients with an abnormal GTT. If postprandial glucose values were >125 mg/dl, the patient was given a printed diet sheet outlining an 1800-calorie, 90 gm protein diet. She was retested 1 to 2 weeks later. Only two patients required insulin to keep the postprandial glucose values in the normal range.

We were interested in determining whether the results of standard glucose challenge testing and 3-hour oral GTT correlated with the outcome of the pregnancies, specifically in relation to rates of fetal macrosomia, birth weight, birth trauma, and cesarean section rate. We also were interested in the overall cost of this testing in a private practice setting.

Material and methods

Shortly after delivery we obtained the following data by chart review from 608 sequential patients seen from late 1985 through early 1987: maternal age, gravidity, parity, estimated date of confinement, glucose screen date, delivery date, delivery mode (vaginal or cesarean section), birth weight, glucose screen value, classification of GTT if performed (normal, borderline, abnormal), GTT values, maternal weight at registration, glucose screen time, pregnancy or delivery complications, and Apgar scores. Data were not available in all categories for all patients, but patients were not excluded because of incomplete data, because this reflects the realities of clinical practice. For example, glucose screening values were available for 578 of the 608 patients, and details of delivery were available for 591. For purposes of calculating birth weight distributions and cesarean section rates in relation to the various glucose screening parameters, premature births (<37 weeks) were excluded.

Data were entered into a personal computer spreadsheet program (LOTUS 1-2-3, VIP Technologies), and statistical analysis was carried out with the Lionheart Biometrics (Lionheart Press, Inc., Alburg, Vt.) statistical package. Z, F, and χ^2 distributions were used where appropriate. A value of $p < 0.05$ was considered significant.

Interpretation of GTT results was based on National Diabetes Data Group criteria[4] as follows: fasting, 105 mg/dl; 1 hour, 190 mg/dl; 2 hour, 165 mg/dl; and 3 hours, 145 mg/dl. The test was classified as abnormal if any two values were equal to or in excess of these

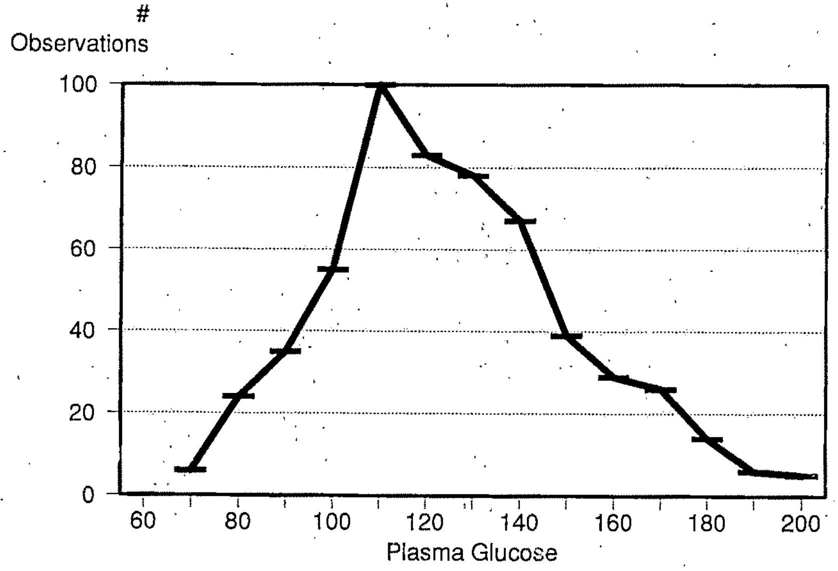

Fig. 1. Distribution of screening glucose values.

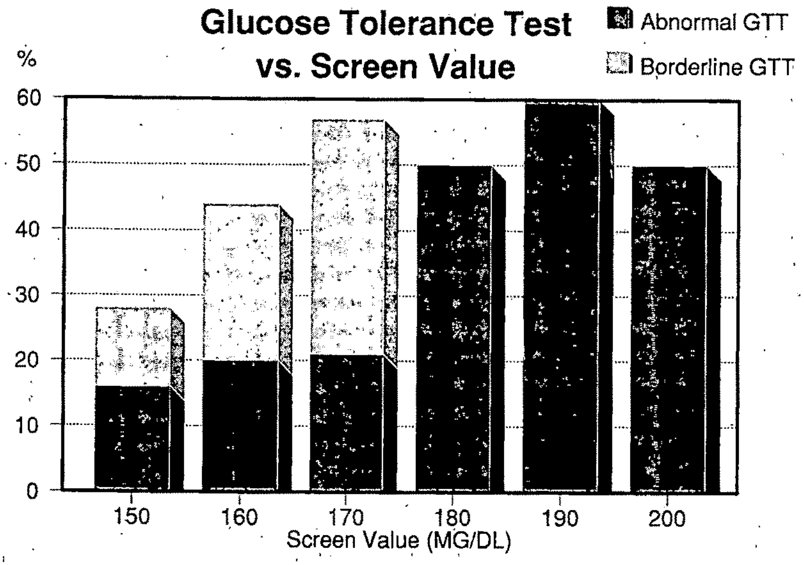

Fig. 2. Percentages of borderline and abnormal GTTs in relation to glucose screen value.

numbers, and the test was considered borderline if any one value was excessive.

Results

Population description. The average maternal age was 27.9, the average gravidity 2.37, and the average parity 0.8. The overall cesarean section rate was 26.7%. After exclusion of breech presentations and repeat cesarean sections, the rate was 18.6%.

Glucose screen results. The distribution of glucose screen values one hour after a 50 gm challenge approximates a normal distribution (Fig. 1) with a mean of 120.7 and standard deviation of 29.0. Thus the value of 150 used as the indication for standard GTT represents 1 SD above the population mean, a value well within the normal population. A value 2 SD above the mean would be 179. Fifteen percent of the population fell above the cutoff value of 150. If 135 had been used as the cutoff, 28% of the population would have required a GTT. If a cutoff of 130 were used, 35% of the population would have required a GTT.

GTT results. Eighty-eight screens were reported as

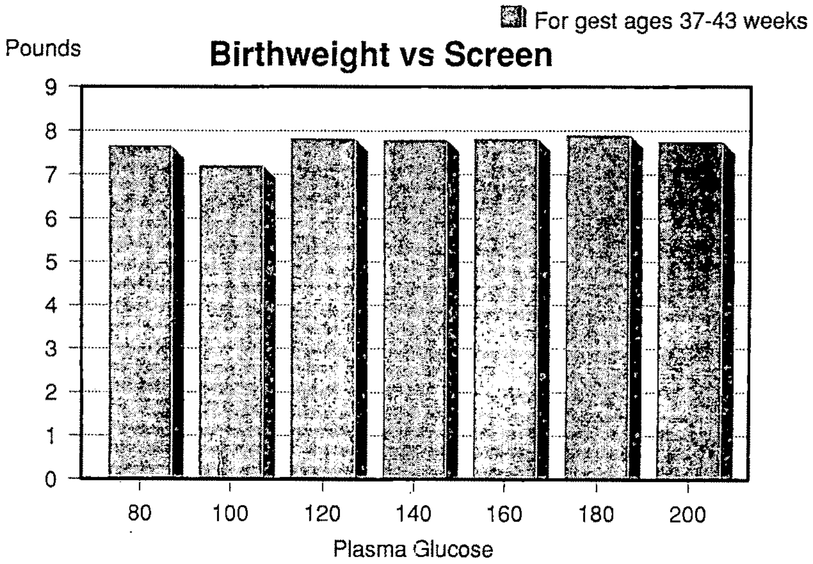

Fig. 3. Birth weight in relation to glucose screen values.

Table I. Birth weight in relation to GTT result

Group	*Birth weight (lb)*		Comparison
	Mean	*SD*	
Whole population	7.69	1.07	Reference
Normal GTT	7.86	1.16	NS
Borderline GTT	7.50	1.15	NS
Abnormal GTT	7.89	0.8	NS

NS, Not significant.

≥150 (15% of the total population). Of these, 83 glucose tolerance tests were performed with the following results: 48 normal, 14 borderline, and 21 abnormal. These results, as well as the frequency of abnormal and borderline GTTs, are shown in Fig. 2.

Birth weights in relation to glucose screening. The birth weights in relation to glucose screen values are shown in Fig. 3. Note that glucose screening values do not predict birth weight in this population. The average birth weight for the entire population is 7.69 pounds, with standard deviation of 1.07 pounds. The birth weights for the subgroups with abnormal glucose screening parameters were not different from this average (Table I).

The distributions of birth weights by GTT category are shown in Figs. 4, 5, and 6. These distributions indicate that the birth weights from the GTT subgroups are not different from those of the population with a normal screen. It is important to note that the gestational ages at delivery were similar for all the subgroups.

Cesarean section rates. Excluding repeat cesarean sections and cesarean sections for breech presentation, the rates of cesarean section delivery for the subgroups are shown in Table II. The cesarean section rates are similar in all groups; i.e., glucose screening parameters did not predict cesarean section delivery rates in this population.

Fetal macrosomia. The numbers of infants weighing ≥4000 gm (8.81 pounds or 8 pounds 14 ounces) are presented in Table III. Glucose tolerance parameters did not predict macrosomia in this population.

Maternal age in relation to glucose screening. Table IV shows maternal age parameters in relation to the glucose screening results. The youngest patient with an abnormal GTT was 22 years of age. Three patients out of the 21 with abnormal GTTs were <28 years old (14%). Only one patient was <24, and 8 patients were <30. Therefore, if age were used as a screening indication, the sensitivities shown in Table V would have been found.

Maternal weight and glucose screening. Table VI

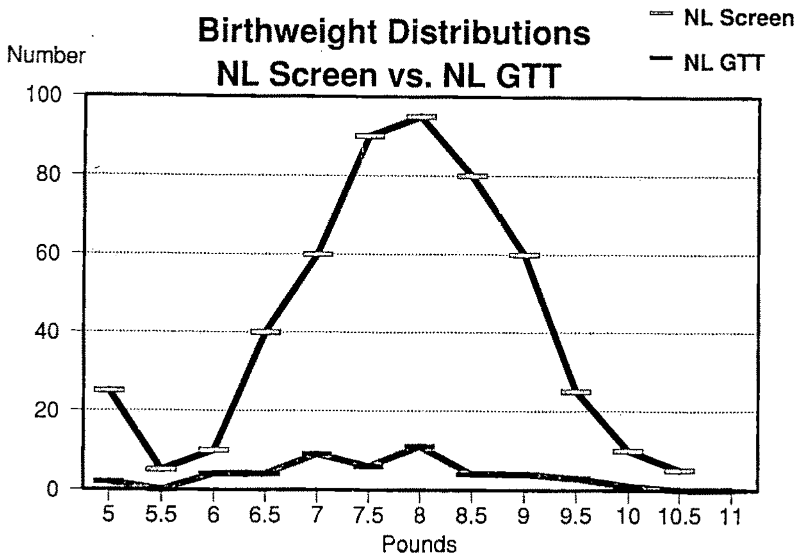

Fig. 4. Birth weight distribution: normal screen versus normal GTT.

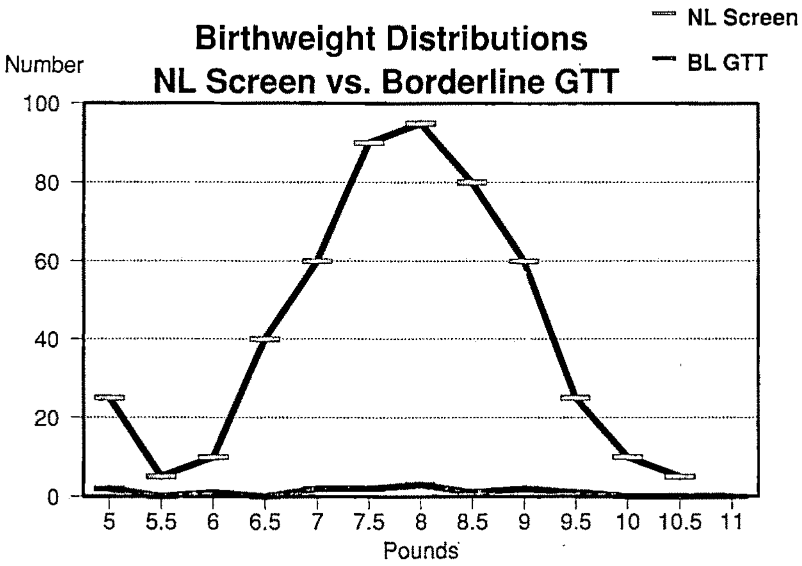

Fig. 5. Birth weight distribution: normal screen versus borderline GTT.

Table II. Cesarean section rate in relation to GTT result

Group	*Cesarean section rate*
Whole population	18.6%
Normal GTT	21%
Borderline GTT	15%
Abnormal GTT	20%

shows the maternal weight values in relation to glucose screening parameters. Maternal weights did not predict abnormal screening results or results of GTTs. If anything, the patients with abnormal glucose tolerance gained less weight in the third trimester than did the others. This may have reflected dietary counseling, which was systematically done only in the third trimester.

Comment

It would not be expected that the minimal management used in this study would completely eliminate pathologic conditions associated with abnormal glucose metabolism in pregnancy, and therefore the results of this study suggest that standard glucose challenge testing practices do not predict these conditions (fetal macrosomia, birth trauma, cesarean section delivery) with enough sensitivity to be cost-effective in a routine private practice setting. Instead, dietary advice given

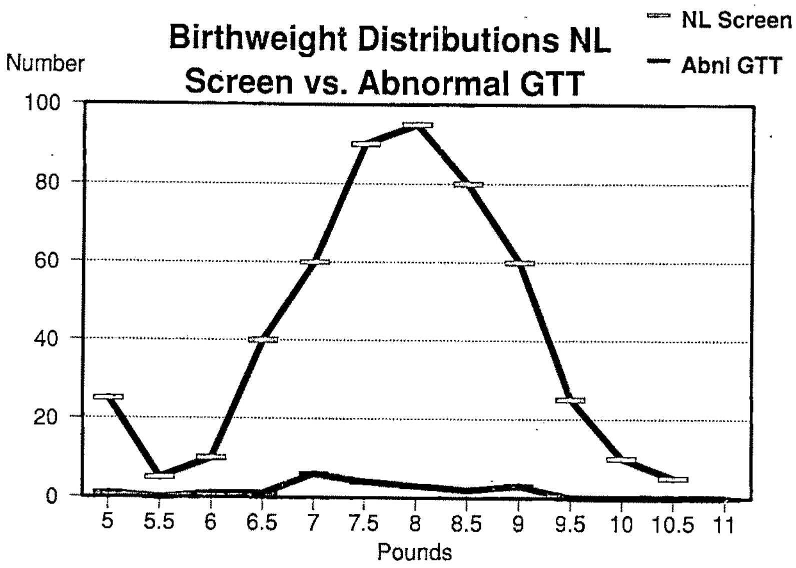

Fig. 6. Birth weight distribution: normal screen versus abnormal GTT.

Table III. Fetal macrosomia (birth weight >4000 gm) in relation to GTT result

	Macrosomic infants			
Group	*Total No. of patients*	*No.*	*%*	*Expected No.*
Screen <150 mg/dl	501	70	14	74.1
Normal GTT	48	8	17	7.1
Borderline GTT	14	1	7	2.1
Abnormal GTT	21	4	19	3.1

Based on rate for whole population.

to patients with elevated postprandial blood glucose levels in the third trimester might seem to eliminate the need for challenge testing. This concept is supported by the work of Lind.[5] Birth trauma did not occur in this study, and there were no significant neonatal complications.

Weingold et al.[2] state that routine glucose testing is cost-effective but do not substantiate the concept with cost per test or cost per case or cost per case of gestational diabetes diagnosed. Swinker[6] reports a cost per patient screened and a cost per case diagnosed as $10.00 and $173.00, respectively, using 130 mg/dl as the cutoff value for 3-hour glucose tolerance testing. Marquette et al.[7] report a cost of glucose screening to be $2.45 per patient, and GTTs to be $11.00 in a 1985 study. Lavin[8] reports a cost of $4.75 per patient screened and a cost of $328.96 per case of gestational diabetes detected. Our cost was $17.75 per screen and $59.15 per GTT, giving our patients a total cost of $10,259.50 for 578 screens, $4904.00 for 83 GTTs, and a cost per diagnosis of gestational diabetes of $722.31. This cost would be significantly higher if we had chosen a lower cutoff value for the 1-hour screen.

Table IV. Maternal age in relation to glucose screen result

Group	*Average age (yr)*
Screen <150 mg/dl	27.5
Normal GTT	30.8
Borderline GTT	32.9
Abnormal GTT	30.5

Table V. Screening sensitivity in relation to maternal age

Age (yr)	*Sensitivity (%)*
≥24	95
≥28	86
≥30	62

One might cut costs by limiting the screening to older patients, but costs would still be high and accuracy questionable. If, as Marquette[7] suggests, only patients ≥24 years of age were tested, we would have a sensitivity of

Table VI. Average maternal weight versus glucose screening result

Group	*Initial weight (lb)*	*Screen weight (lb)*	*Delivery weight (lb)*	*Total gain (lb)*	*Third-trimester gain (lb)*
Normal screen	140.7	164.7	171.8	31.1	7.1
Normal GTT	142.9	162.5	173.2	30.3	10.8
Borderline GTT	143.1	162.2	169.4	26.2	7.2
Abnormal GTT	142.2	159.4	164.5	22	5.0

95%. He reported a sensitivity of 83% with this age criterion. If only patients >30 years were tested, we would have a sensitivity of 62%.

Elevated maternal weight and excess weight gain were not predictors of abnormal glucose tolerance, increased birthweight, or cesarean section rates.

Jovanovic and Peterson[9] report that 27.7% of their patients with a glucose screen >150 mg/dl at 27 to 31 weeks' gestation were delivered of infants weighing ≥4000 gm. Our number was 15.2% for all patients with a glucose screen >150 mg/dl, which was comparable to the rate of 14% in patients with a screen of <150 mg/dl.

In conclusion, the results of this study cast doubt on the current approach to gestational diabetes. We have been led to believe that challenge testing will help in the management of pregnancies and that therapies based on these tests are beneficial. This study does not support this concept. Fetal weight, morbidity, difficult delivery, and maternal morbidity were not different in the various groups defined by glucose challenge testing. Costs of challenge testing are substantial and probably do not contribute to improvement of fetal or maternal outcome.

We feel that postprandial glucose measurement at the time of other routine blood testing in pregnancy would cost less and give us the physiologic values we actually use to manage patients. Routine third-trimester dietary counseling and aggressive induction of labor for postdate pregnancies or suspected fetal macrosomia might help eliminate the pathologic conditions associated with gestational diabetes.

We do not feel, as did Hunter and Milner,[10] that "gestational diabetes is a diagnosis looking for a disease" but rather that gestational diabetes is a disease looking for a diagnosis.

Discussion

DR. JOHN ENBOM, Corvallis, Oregon. This study group involved data on 608 obstetric patients in a 2-year period given a 50 gm, 1-hour, postprandial glucose challenge and, further, a 100 gm GTT in those with values found to exceed 150 mg/dl on the screen. Eighty-three (15%) had an abnormal screen and were compliant in follow-up; 48 (7.9%) studies were normal, 21 (3.5%) were abnormal, and 14 (2.3%) were borderline. Gestational length appeared to relate to macrosomia, and advancing maternal age with an increasing incidence of operative delivery. No birth trauma, fetal morbidity, or neonatal hypoglycemia was noted.

The resulting study group, 21 patients with the diagnosis of gestational diabetes out of 608 screened patients, points out the need for a larger patient population or collaborative studies to evaluate the multiple factors related to morbidity and mortality of gestational diabetes. I do find it interesting that maternal weight gain was reduced in the third trimester after diagnosis and the initiation of a diabetic diet; this points out the importance of motivation when the patient is confronted with a diagnosis that presents potential risk to her fetus.

The authors chose a screening level of 150 mg/dl as their abnormal cutoff, to increase specificity in the screened group. This level may have validity, but unless a lower screening value such as 135 to 140 mg/dl is used to substantiate the specificity and sensitivity of a group, I don't feel one can rely on the assumption that this screening level will not miss a substantial number of patients with gestational diabetes. The fact that the screening level was 1 SD above the mean does not answer the question of the total incidence of gestational diabetes in a screened population.

In 1964, when O'Sullivan and Mahan[1] first published their data on pregnancy-induced diabetes, there was definite need for diagnostic criteria for risk management in prenatal care. The contribution of a standardized method of diagnosis and management for gestational diabetes has been invaluable. The continuing importance of this diagnostic area in risk management has been emphasized again in an updated *ACOG Technical Bulletin* from the American College of Obstetricians and Gynecologists,[2] recommendations from the Centers for Disease Control in 1986[3] and the Second International Workshop Conference of Gestational Diabetes Mellitus in 1985.[4] In all guidelines the emphasis is on diagnostic criteria and, after this diagnosis, a management scheme.

Cost in diagnosis and management are important areas that I feel were brought out in this paper and need to be further addressed. The cost of diagnosis in this article was $722.37 per case of gestational diabetes and would have been higher if a lower screening value had been chosen. This is essentially twice the figure stated in Everett's article on screening for gestational diabetes.[5] It would have been beneficial to see the cost figures for screening levels of 135 and 140 mg/dl as well. Everett suggested further research should be focused on decreasing the cost of screening for gestational diabetes. Wouldn't it be better to screen all patients in a more cost-effective and clinically significant manner?

If patients who maintain a normal fasting and 2-hour postprandial blood glucose have a low perinatal mortality rate[6] and postprandial glucose studies after normal dietary intake may be more physiologic, it follows that evaluation of the parameters of treatment is a more effective and cost-efficient method, as suggested by Schneider and Cevert.[7] They have suggested the term pregnancy-induced glucose intolerance and use of a postprandial level of 120 mg/dl. Other authors have suggested similar screening of postprandial blood glucose levels for diagnosis and follow-up of patients on diet management.

The question of the later predictive value of the current gold standard in diagnosing diabetes mellitus, the 100 gm GTT, has also been brought into question by Naylor,[8] who suggested only a 36% positive predictive value for this diagnosis after delivery in a highly selective group with glucose intolerance during and after pregnancy and the need to consider higher values in the diagnosis of gestational diabetes that may correlate with future diabetes mellitus in a more predictive manner.

With increasing costs and reduced relative health dollars, we must increase our efficiency in the cost of diagnosis and apply more stringent criteria for the clinical diagnosis of gestational diabetes.

I would like to ask Dr. Bolton the following: (1) Do you still feel that a screening value of 150 mg/dl is the most effective cutoff value, regardless of the cost of screening? (2) Were all newborns screened for hypoglycemia or only those that appeared symptomatic? (3) How does your group currently screen for gestational diabetes in your office population? Would you suggest different guidelines?

Dr. Bolton (Closing). I am very pleased to have not been bombarded with technical questions from the perinatologists.

Dr. Enbom, our thesis is that the cutoff value used for screening, at least in the ranges we tested, does not seem to make much difference. Although some obstetricians in Portland are now using 130 or 135 mg/dl, it would cost more to do GTTs on women whose screening tests are at that level. As a result of this study, we will no longer screen women younger than age 24. We will, however, monitor postprandial blood glucose values on all mothers throughout pregnancy. In this study the blood glucose values were checked only for babies who were symptomatic, and we tracked these through the pediatricians. The babies got along quite well.

The problem in monitoring gestational diabetes is we are on the outside looking in. We indirectly study the fetus by checking maternal glucose, hemoglobin A_{1c}, and fructosamine, while what we really need to know is the level of fetal insulin. Of course, we do not have a very good handle on that because insulin, being rather uncooperative, does not cross the placenta. A recent study[1] from Graz, Austria, reports a large number of amniotic fluid insulin determinations. It clearly shows that when fetal insulin is normal there is no problem. The group of gestational diabetic patients in whom the fetus has elevated insulin concentrations is the problem. We need to find a practical, noninvasive method to discriminate between the two groups, but for the moment, we do not have it.

Alternative liability insurance: A physician-owned captive insurance company

George F. Lee, MD
San Francisco, California

The physician-owned captive insurance company is a lesser known but dynamic alternative to commercial insurance. The Physicians Reimbursement Fund, Ltd., was founded in 1975 in response to the malpractice crisis of that year. The company insures about 100 physicians in high-risk specialties. Approximately one half are obstetrician-gynecologists. Innovative management has enabled this company to operate successfully at a fraction of the premium charged by typical insurance companies. Fourteen years of experience have demonstrated the ability of this company to successfully serve the needs of the community. (AM J OBSTET GYNECOL 1991;164:1680-5.)

Key words: Liability insurance, captive insurance company, physician-owned insurance company

In 1975 both the cost and availability of medical liability insurance reached crisis proportions in California. Commercial insurance carriers withdrew from the marketplace, leaving many communities in Northern California with no alternative for malpractice insurance.

One solution to this problem was the formation of "doctor-owned" insurance companies. These companies were able to restore availability of malpractice insurance to the physician community. Cost, however, remained a problem for some specialties. This has been particularly true for the field of obstetrics.

Currently, commercial carriers only offer claims-made policies. Claims-made policies, in contrast with occurrence policies, may require the purchase of a tail when a physician decides on a career change. As a result of these financial considerations, some obstetricians have chosen to go "bare." This option is not in the best interest of the patient or the physician. On the positive side, California's 1975 Medical Injury Compensation Reform Act has had a profound effect on stabilizing the previously escalating costs of liability insurance. California's legislative reform package has become a model for the rest of the United States.

Alternative solution

A less understood alternative to both the commercial market and the doctor-owned companies is the "captive insurance company." By definition, a captive insurance company is a wholly owned or controlled subsidiary company formed primarily to insure the risks of its noninsured parents or affiliates. An "offshore captive" is incorporated in a foreign jurisdiction and operates out of that foreign location while primarily insuring the domestic risks of its parent. The parent may be an individual, a company, or an organization of individuals with a common insurance need.

The Physicians Reimbursement Fund, Ltd., is an offshore captive insurance company incorporated in the Cayman Islands of the British West Indies in 1975. This company serves the interests of its founding physicians, who are approximately 100 high-risk specialists who practice in the City of San Francisco. About 50% of the physicians insured by this company are obstetrician-gynecologists. As a result, the management and experience of this company reflect the experience of this specialty.

The impetus to form the company arose early in 1975 when it appeared that there would be no viable insurance carriers in the San Francisco Bay area. The main objectives were and remain: (1) ensure availability of malpractice insurance; (2) contain costs; (3) embody the principles of California's 1975 Medical Injury Compensation Reform Act; and (4) offer an occurrence-based policy. A guiding principle of this insurance company is the mandatory requirement for all participating physicians to use binding arbitration.

After a careful analysis, Grand Cayman of the British West Indies was chosen as the site of incorporation. The offshore site offered a number of advantages including minimal capital requirements, minimal regulatory requirements, a stable economic and political history, readily accessible air travel, and professionals schooled in the formation of captive insurance companies.

From the Department of Obstetrics and Gynecology, Pacific Presbyterian Medical Center.

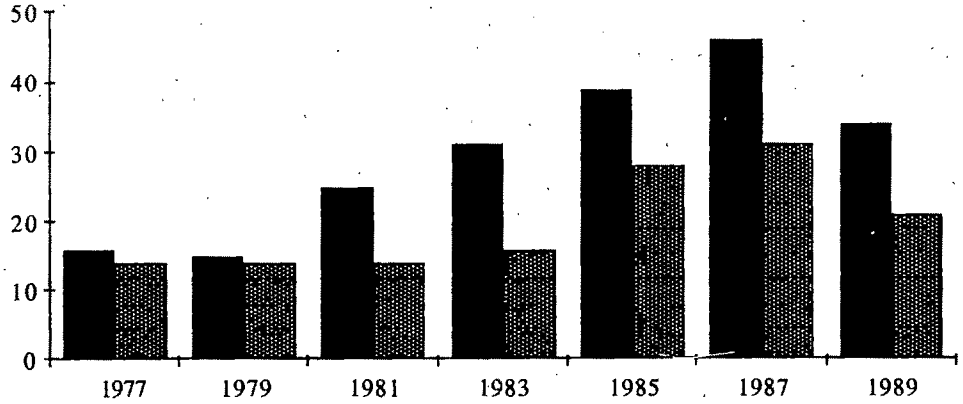

Fig. 1. Physicians Reimbursement Fund, Ltd., claims experience. *Solid box,* Incidents reported; *stippled box,* claims and active cases.

Organizational format

The relationship between the onshore and offshore components of an operating captive insurance company is moderately complex. Whereas the Physicians Reimbursement Fund, Ltd., is incorporated and performs all its insurance duties at the offshore site, management of claims and educational support to the physicians are performed in San Francisco through the auspices of the Patient Protective Association. The Patient Protective Association is a California nonprofit corporation. It acts as agent for those insured. To comply with California regulations it is essential to separate the various functions and compartmentalize them according to state requirements. Appropriate legal, accounting, and actuarial services are readily available to management in day-to-day operations. In this capacity management uses the same guidelines as any domestic insurance carrier with respect to underwriting and investment policies. A board of directors comprises four physicians, three of whom are members of this Society, and provides all the management services for the company. On the basis of the requirements of the 1986 Tax Reform Act, the company elected to be treated as a U.S.-based insurance company for tax purposes.

Premiums

The Patient Protective Association, acting as agent for the physicians, collects all premiums and transmits them to the insurance company in Grand Cayman. Each physician pays an initial premium of $2000, and during the first 12 years paid an annual premium of $6000 ($500 per month). The limits of insurance during those years was $250,000 per occurrence and $600,000 per year. All physicians regardless of specialty were treated equally. In 1987 the limits of insurance were increased to $500,000 and the premium increased to $12,000 per anum ($1000 per month). At this time, all premiums paid to this company remain on deposit as reserves for future claims. To date, all operating expenses, settlements, and awards have been paid out of the earnings from the company's reserves. The Physicians Reimbursement Fund, Ltd., is managed by four physician members of the Board of Directors. Legal counsel in Grand Cayman provides office space and secretarial support staff. All funds are deposited in Bank of America, Grand Cayman. Accounting services are provided by Coopers and Lybrand, Grand Cayman. Actuarial services are provided by The Wyatt Company, San Francisco. The total cost of managing the insurance company is approximately $100,000 per year.

Claims management

The Patient Protective Association provides educational support services and undertakes to manage claims on behalf of the insured physician.

The office of the Patient Protective Association is located in San Francisco. Staffing for the Patient Protective Association requires one part-time bookkeeper and a full-time chief executive officer. Total operating costs for managing the Patient Protective Association are approximately $90,000 per annum. These funds are derived from dues paid by the physician members of the Patient Protective Association. Each member is assessed $100 per month.

Claims experience

Claims experience for the Physicians Reimbursement Fund, Ltd., has been remarkably predictable over the past 14 years. From 1976 to 1987 there was a gradual increase in the number of incidents reported. This reflects an increased awareness of the physician members and their willingness to assist the company in performing its services. Physicians are encouraged to report any incident that might eventually turn into a legal action. Actual claims have likewise shown a gradual increase

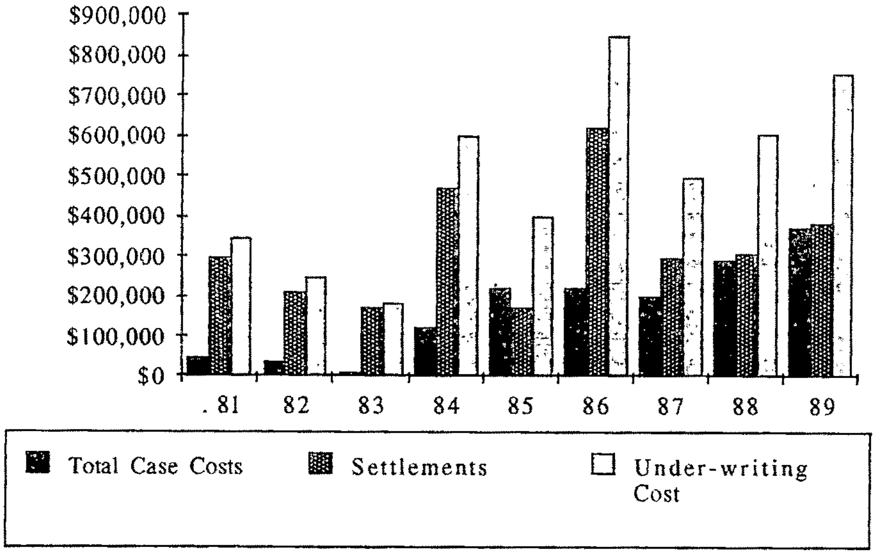

Fig. 2. Physicians Reimbursement Fund, Ltd., major claims losses.

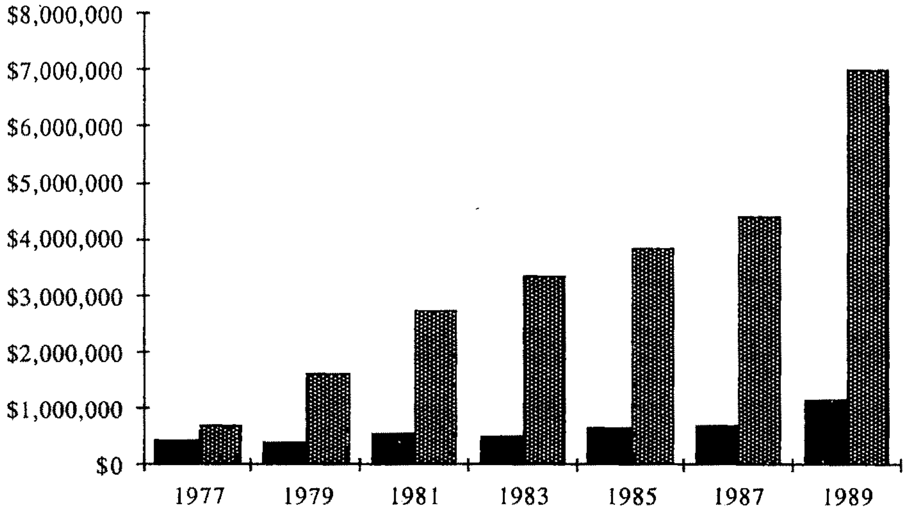

Fig. 3. Physicians Reimbursement Fund, Ltd., premiums paid and reserves. *Solid box,* Premiums paid; *stippled box,* reserves.

through 1987 and a subsequent softening during the past 3 years. These trends are comparable to the national experience (Fig. 1). Total case costs, settlements, and underwriting costs have slowly increased over the life of the company. This reflects increases in filed claims and legal costs (Fig. 2). The incidence of claims filed against physicians in this company is about equal to that of the national average. Despite this fact, the company has been able to service the needs of the physicians and the patients at a substantially reduced premium. It is our estimate that over the life of this company, the average obstetrician has saved approximately $260,000 in premium costs. The ultimate beneficiary is the consumer, our patient.

Total reserves for the company are approximately $9 million. This represents about $100,000 per insured physician, and compares very favorably with the commercial carriers in California.

Management principles

Management believes that the success of this company is a result of careful adherence to the provisions of the Medical Injury Compensation Reform Act, including the vigorous use of arbitration. In addition, there are three unusual features of this company's operations.

1. Peer visibility. All those insured work in the same community. Each insured is expected to donate time to the organization for claims review or committee work. This tends to promote a high level of consciousness concerning suit prevention.

2. Code green. Physicians are encouraged to intervene actively in suit avoidance and problem resolution. At a physician's request, the company will reimburse a patient for economic loss as a result of complications or maloccurrence (i.e., excess hospital costs, home care, lost wages, repair of dental crown). No release is required from the patient.

3. In-house case management. Most of the company's claims are handled by a claims committee composed of physicians. Very few cases are handled by legal defense firms, and when they are the progress of the case is monitored very closely, including the need for depositions and expert reviews.

By virtue of an aggressive approach to settling cases, only four cases have gone to arbitration and two cases to trial during the 14-year history of the company. All but one of these cases were won by the defense.

Comment

The Physicians Reimbursement Fund, Ltd., is an example of a small but effectively run offshore captive insurance company. In a volatile market it guarantees availability and has shown an ability to control costs. Whereas it is not commonly understood, there are many physician groups, hospitals, and clinics across the United States that successfully use this model to provide liability insurance. At a time when many obstetricians face escalating insurance costs, a captive insurance company is a viable alternative.

Special consideration is given to Ms. Linda Osborne for her creative assistance.

Discussion

Dr. Keith P. Russell, Los Angeles, California. I have two questions: (1) How many physician-owned captive companies are there in the United States? I know of a number owned by organizations, but I am inquiring about pure physician-owned companies. (2) What is your application process for physicians? Is there a selection or can anyone join?

Dr. Russell K. Laros, San Francisco, California. Are payments made to patients by your company exempt from the new national legislation that requires reporting to a national data bank? Are you concerned that with the requirement for reporting any sum given to patients, physicians will be less willing to make payments and settlements? Do you anticipate growing reluctance on the part of your physicians to participate in code green?

Dr. Theodore W. Loring, Eureka, California. I congratulate Dr. Lee and his associates for designing and forming this alternative liability insurance company for high-risk physicians, especially obstetrician-gynecologists. Dr. Lee told us the reasons for selecting the Grand Caymans—minimal regulatory and capital requirements, a stable economy and political history, and professionals schooled in the formation of captive insurance companies. These professionals have been well compensated for their efforts in the offshore captives.

The period 1975 to 1980, coinciding with our California malpractice crisis, was an era of experimentation in providing insurance. The exodus of commercial companies, not the physician-owned companies, caused introspection by physicians from which came many different forms of insurance. Before that time, claims-made insurance did not exist. The offshore captive insurance plans became numerous. In contrast with Dr. Lee, I believe that captives are not widely distributed throughout the United States, and that there have been many failures among them. Many people formed captives, nonphysicians and unfortunately some physician entrepreneurs. After a time many of these companies folded, but the investors still made a lot of money. This is because in the malpractice insurance business few claims of significance surface before 3 to 5 years after a policy is issued. Were this Society, for example, to form a captive company and begin to collect premiums today, it would be 3 or 5 years before we would have to pay any significant amount of money in claims. During the interval, our income could be invested and from investment income we could pay small claims. This is just what the physician's captive in San Francisco has done.

Physicians and their patients both need protection. Therefore when an insurance company is licensed by most states it must meet certain requirements. In California we have had quite a few companies fail since 1975, but there is a state Insurance Guarantee Fund to which every licensed insurance company must contribute. Every company licensed to sell insurance in the state—medical malpractice, automobile, homeowners, or whatever—is assessed to be sure that people who need protection will get it should a company fail. The fund relieves the physician of liability if an insurance company fails. Offshore captives do not have to meet these requirements.

This company provides coverage on an occurrence basis rather than a claims-made basis, and this gives the physicians who belong to it some long-term protection. In 1975, stock companies left California in droves and there are now just two that function in California. Stock companies sell their stock to the public and must make a profit to be successful. If by chance they have a bad year, either in underwriting or in investments, premiums for the next year are increased. Profits, when they do occur, go to stockholders, not to the insured physicians. The stockholders of a mutual company, on the other hand, are the insured. Profits, if any, are distributed to the insured as dividends. In California, insurance exchanges have a mix of features of stock and mutual companies. In addition, there are cooperatives that are not insurance companies and therefore are not controlled by the state insurance laws.

Dr. Lee's company, which insures 90 to 100 physicians in high-risk specialties, would not be appropriate for the general medical population. Despite insuring those at high risk, the company succeeds because it is run by a very dedicated group of people. Physician involvement in management, particularly on the board, and in underwriting and claims management are important factors. They review the insured physicians as peers. In looking at a claim, the doctor can easily envision himself or herself in the defendant's position.

I am surprised that you have been able to maintain a $250,000 claim limit until 1987 and $500,000 since then. You must have had charmed lives during a period of megaawards in cases involving infants with neurologic deficit. Fortunately, in the past 3 years, doctor-owned companies in California have had a great claims experience. In 1989 and again in 1990, premiums were reduced, even for obstetrics. The company with which I am involved expects a significant further decrease in 1991.

Dr. Lee, I have several questions about your presentation: (1) The number of members has remained about the same or declined a bit since 1985. Is this because of underwriting rejections? (2) Are the claims shown in Fig. 3 still open or have they been closed? For example, for 1983 the chart shows approximately five claims and 10 active cases. Is this a total of 15 cases? (3) In Fig. 4, does the total underwriting cost include the total case costs and settlement costs, or just the underwriting costs? (4) You mention a 14-year history of success with arbitration. Why did you have two cases that went to trial? My understanding is that when the patient signs a binding arbitration agreement, she must accept the decision of the panel.

Dr. Carl Goetsch, Berkeley, California. As president of the California Medical Association in 1975, I am a bruised and battered survivor of the professional liability crisis. In 1950 I began to do case evaluation and defense for a program underwritten by American Mutual Insurance that covered all the Northern California counties. Some years the company lost a little money, but on average they came out very well. Two or three years before the crisis of 1975, the premiums rose sharply. Basically a workmen's compensation company, they pulled out of the professional liability business when the insurance commissioner of Massachusetts said they must put more in surplus. Therefore I think it is important to consider a program's long-term history before you evaluate its efficacy. Your company is successful, at least it is still viable. Nonetheless, we are not yet in a position to evaluate this method of coverage as a particularly good or bad way of approaching the problem. For one thing, your group is so small that the law of averages has not had full play. Dr. Lee, is the contract for this company assessable?

Dr. Lee (Closing). One tenet basic to the formation and operation of this company was to assure the availability of insurance. When we first developed the idea, the commercial carriers had withdrawn and the doctor-owned companies had not started. Over the years, pride of ownership on the part of most of the physicians in the group has maintained the company.

Dr. Russell, I do not know how many captive companies are owned by physicians in the United States. We are closely allied to six companies in California and I am aware of a number of other companies through our attorneys in the Grand Caymans. My reading in the *Wall Street Journal* about the Harvard Community Hospital program, one of the largest programs formed in the Grand Cayman Islands, was what prompted my investigation of offshore captives. After we looked at the Bahamas and other places in the Caribbean and Europe, we selected the Grand Caymans because of the good reputation it had from people who had actually worked with the people there.

Dr. Laros, you hit on my most worrisome management problem for the next 10 years. The federal government will soon require the reporting of any money paid on behalf of the patient. Fortunately, we think there will be two exceptions. First, you can write off your bill, even a big one. Second, we can reimburse for out-of-pocket spending. There is also a gray zone that will allow individual companies to interpret what is reportable. Attorneys from many companies including ours are working hard to establish criteria. What we have done with the code green concept is to make the patient satisfied and not worried about who is right or wrong. It works and is a valuable part of what we do. Its loss would put us, and all of medicine, in jeopardy. I think we will retain some of it because our message will be heard at the national level.

Dr. Loring, it is true that a captive insurance company can be set up for inappropriate purposes, retirement plans or tax shelters. It is also true that if a captive insurance company fails, people are left in the cold, as with any business. We do not participate in the California insurance fund. Because this is a doctor-owned company, each of the owners has full knowledge of its statistics. The insight that each person has and the ability of each to participate, contributes to management's decisions with respect to ensuring that there are adequate reserves. This serves as a major force for the company to do what is in the best interest of the physician owners. If we were to close the company tomorrow and take no more premiums over the next 8 years (i.e., the statute of limitation), we could probably live off of the earnings from the company and still return to all the physicians every dollar they ever put into it. In this company there is probably a higher percentage of reserves per doctor than in most commercial companies. Because we do not have a large company to back us up if we go bankrupt, management is intense and it is imperative that we maintain a high level of reserves.

The most important mark of our company is that physicians participate in the decision making and contribute to how the company operates. Because they are aware of the day-to-day operation of the company and know what is happening in the marketplace, it is not likely that the company is going to leave people high and dry.

The intensity with which the group responsible for physician selection looked at each other's risk level was extremely high when we started in 1975. Since then we have had no interest in growing in numbers. It is only to serve the interests of the physician group that the company exists. When a member retires, a replacement is drawn from the medical community, perhaps someone joining an existing practice. Most are relatively fresh from residency and have no track record that can be used to assess them. Our experience over the past 15 years has not been remarkably different from the national experience in terms of suits and claims filed.

You mentioned that it may take 5 years for claims to surface. In 15 years we have had only one claim surface more than 12 months after the incident and that was at about 14 months. We have been able to predict our future losses accurately. Because there is a statute of limitations in it, the arbitration contract probably has a role in making these claims surface early. However, I reemphasize that we do stand alone. It is not a perfect system and there is a bit of risk in it.

You noted our limits. The structured award part of current California medical liability law is extremely important to us. A structured award of $200,000 put on the table today results in $3.2 million over the life span of an injured child. In California, the total multimillion dollar award is not the cost to the insurance company as it is in New Jersey, for instance, where the award is paid up front. The fact that in California the award is paid on a monthly basis over the life span allows us to have a lower limit and still service a higher payout.

Dr. Goetsch, each physician is assessable for $6000. When we started the company we needed a guarantee from each person to pay 1 year's premium, $6000 in case we had miscalculated our costs over the next 5 years. We have not needed to collect it over the 15 years. Being assessable for $6000 is still written into the contract and there has been no problem with acceptance by new members. If the company should go bankrupt, we would need that amount to satisfy outstanding obligations. Thus although we would hate to pay it, the money would be there to pay on our behalf for the company's obligations.

LETTERS TO THE EDITORS

Residency training and abortion

To the Editors: The article on obstetric ethics and abortion (Chervenak FA, McCullough LB. AM J OBSTET GYNECOL 1990;163:1425-9) is an interesting presentation on ethical issues relating to abortion. In closing the authors discuss the implications for obstetric residency training programs. Whereas I agree that no resident should be forced to perform abortions, training in the technique of abortion should be a standard component of obstetrics and gynecology residency training programs. Currently, relatively few programs require abortion training; most simply make such training available on an optional basis for those who request it. Given that abortions in the United States are performed primarily by obstetrician-gynecologists, it is imperative that all be trained in this procedure. We do not give residents the option as to whether they will be trained in the technique of vaginal or abdominal hysterectomy or of any other procedure commonly performed by obstetrician-gynecologist specialists.

Clearly, there must be an option to allow those who truly are opposed to abortion for religious or other reasons not to have to perform the procedure. However, for all others it should be required and should be listed as another required procedure when programs are reviewed by the Residency Review Committee. It is imperative that obstetrician-gynecologists be trained, particularly in second-trimester procedures, because they are the only physicians who will be doing these more complex procedures.

Dilatation despite cervical cerclage: A diagnostic pitfall

To the Editors: The risks of uterine contractions in the presence of cervical cerclage are laceration of the cervix and rupture of the uterine corpus. We observed a case of a paracervical uterine rupture with extension to the vaginal fornix, presenting as if it were an effaced and dilated cervix.

A 24-year-old gravida 4, para 0, abortus 3 woman had a Shirodkar procedure in week 19 of pregnancy because of cervical incompetence in association with twin pregnancy. At 27 weeks' gestation, the patient was admitted to the hospital with painless vaginal bleeding. Ultrasonography excluded placenta previa. Biamniotic twins were seen: the lower child in breech presentation and the other in transverse lie. Speculum examination and vaginal palpation did not demonstrate the presence of the suture, and 3 cm cervical dilatation was felt. Some hours after admission, premature contractions started and an intravenous ritrodrin treatment was instituted.

In spite of tocolysis progression of labor was noted. The membranes ruptured spontaneously and dilatation proceeded to 7 cm. Cesarean section was performed after induction of general anesthesia. The first infant, a girl in breech presentation, weighed 910 gm and had Apgar scores of 7 and 8 at 1 and 5 minutes, respectively, and an umbilical artery pH of 7.31. The second infant, also a girl, weighed 900 gm, had Apgar scores of 6 and 7, an umbilical artery pH of 7.33, and was extracted in breech presentation after version from transverse lie. Both infants were immediately transferred to the neonatal intensive care unit.

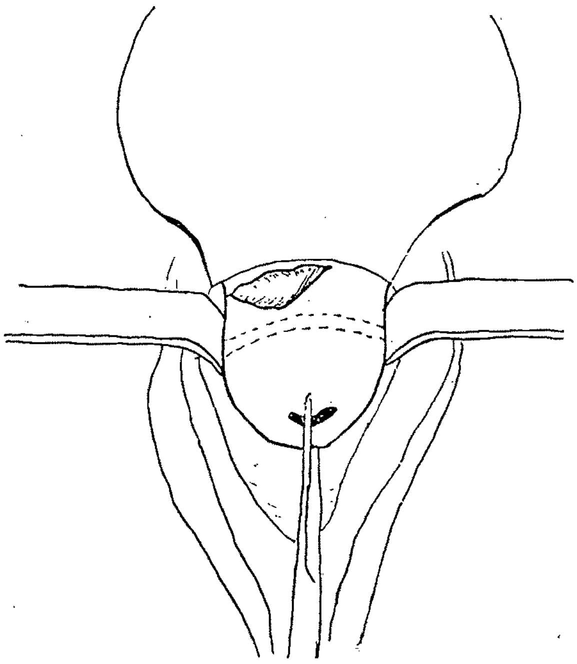

Fig. 1. See text for explanation.

At surgery it became evident that the cervix was still closed with an intact ligature, but there was a 6 cm paracervical uterine rupture extending from the attenuated lower posterior segment to the left lateral vaginal fornix (Fig. 1). Some minor oozing from the edges of the lesion was noted. At vaginal examination this rupture must have been considered an almost completely effaced and dilated cervix. The site of the uterine rupture was abdominally sutured, thereafter the forniceal lesion was closed transvaginally and the ligature was removed. The patient recovered well; the infants' neonatal development was favorable.

To our knowledge this is the first reported case of paracervical uterine rupture resulting in a false way to the vagina in the presence of a closed cervix with the ligature in place. The only more or less comparable case was reported by Pelosi et al.[1] They describe a successful vaginal delivery through a preexisting cervicovaginal fistula. There was no preexisting fistula in our patient. The reported incidence of cervical laceration after cerclage has been performed varies from 1% to

13%.[2] Interpretation of the vaginal examination created some specific difficulties: careful inspection did not show the ligature or its knot and it was not found at palpation. The cervix was compressed against the upper vaginal wall and the rupture presented as if it were a centrally positioned, dilated cervix. The patient showed none of the classic clinical signs and symptoms of uterine rupture.

When a patient known to have a cervical cerclage presents in preterm labor and effective tocolysis cannot be achieved, the ligature must immediately be removed. If it is impossible to visualize the ligature in the presence of dilatation, a paracervical rupture must be considered before deciding the suture has broken.

Cytomegalovirus infection

To the Editors: I agree with Drs. Grose and Weiner (Grose C, Weiner CP. Prenatal diagnosis of congenital cytomegalovirus infection: two decades later. AM J OBSTET GYNECOL 1990;163:447-550) that congenital cytomegalovirus infection is a major health problem in need of more attention in the perinatal literature. They conclude that amniotic fluid culture for cytomegalovirus is a useful adjunct when congenital cytomegalovirus infection is suspected. The question is what should be used to raise one's suspicion?

Maternal cytomegalovirus infection, as in two of the authors' cases, may be an acceptable indication for amniocentesis. A second indication is a fetus with ultrasonographic evidence of central nervous system abnormalities—especially because such patients would usually be offered amniocentesis for chromosome analysis anyway. Thus there would be no further potential for procedure morbidity by the addition of a cytomegalovirus culture to the fluid analysis.

Unfortunately, as the authors point out, cytomegalovirus infection in adults, pregnant or not, is usually not significantly symptomatic and therefore is uncommonly diagnosed. Similarly, most fetuses with intrauterine cytomegalovirus infection probably have no abnormalities that are detectable by ultrasonography, although this needs further study. As with toxoplasmosis, the vast majority of suspected congenital infection would be identified only by routine maternal serologic screening.

There are significant differences, however, between cytomegalovirus and toxoplasmosis with regard to those fetuses infected in the first half of pregnancy. Whereas the majority of those infected with toxoplasmosis will have significant postnatal sequelae, only 10% of neonates with positive cytomegalovirus cultures have adverse sequelae. More important, toxoplasmosis therapy has proved efficacy, whereas cytomegalovirus antiviral therapies do not.

Despite the high prevalence of cytomegalovirus in the community, routine maternal serologic screening (the only proved way to identify the vast majority of cytomegalovirus infection) is not generally recommended. This should change with the development of drugs effective against herpes viruses.

Intravenous immunoglobulin treatment of recurrent pregnancy loss and antiphospholipid antibodies

To the Editors: We read with great interest the review by Reece et al. (Reece EA, Gabrielli S, Cullen MT, et al. Recurrent adverse pregnancy outcome and antiphospholipid antibodies. AM J OBSTET GYNECOL 1990;163:162-9). We would like to comment on another possible mode of treatment in these patients by intravenous immunoglobulins.

Immunoglobulins play a central role in immune regulation. Intravenous preparations of immunoglobulin have become available for clinical use in a wide range of diseases including treatment of patients with recurrent abortions of the immunologic type.

Several reports have been published concerning the treatment of recurrent pregnancy loss as a result of antiphospholipid antibodies with intravenous high-dose immunoglobulins[1-4] and are summarized in Table I.[5] Determination of treatment intervals and doses used in these studies were empiric because phospholipid antibody tests did not appear to be useful to monitor therapy. This is probably why the patients were also treated with low-dose heparin and aspirin.

The effectiveness of this new mode of therapy may be related to several immunologic mechanisms such as blockade of antibody binding to receptors on macrophages or antiidiotypic interactions. Preliminary data concerning the efficacy of intravenous immunoglobulin in the treatment of this condition are encouraging but further studies are required to determine the optimal mode of therapy.

Response declined

Follow-up of elevated maternal serum α-fetoprotein levels: Ultrasonography only or amniocentesis?

To the Editors: Because of current discussions that amniocentesis may not be necessary for patients with an elevated level of maternal serum α-fetoprotein (AFP) and a normal level II sonogram,[1, 2] we reviewed the experience in our laboratory in 1989. We receive maternal serum AFP and amniotic fluid specimens for prenatal diagnosis from a broad referral base in the greater metropolitan area of Atlanta.

Fourteen cases of spina bifida–meningomyelocele and encephalocele (collectively referred to as neural tube defects) were detected prenatally during 1989. Anencephaly was excluded from this review because the diagnosis by ultrasonography alone is not in question. Two patients (cases 1 and 2) each had elevated maternal serum AFP levels (6.0 and 3.0 multiples of the mean) followed by a normal level II sonogram at 17 levels and 18 weeks' gestation, respectively. Amniotic fluid AFP was 4.2 and 2.2 multiples of the mean, and each had a positive acetylcholinesterase value. On the basis of these abnormal results, a second high-resolution ultrasonographic evaluation was performed on case 1, and a second and third were performed on case 2 before spina bifida was detected in both fetuses. A third patient (case 3) had a normal sonogram performed before amniocentesis at 16 weeks' gestation because the patient had insulin-dependent diabetes. Amniotic fluid AFP level was 2.1 multiples of the mean and the acetylcholinesterase value was positive. On the basis of this abnormal result, the level II sonogram was obtained and spina bifida was detected. Case 4 had a maternal serum AFP level interpreted as not elevated (2.1 multiples of the mean) at 16 weeks' gestation, normal "routine" sonogram, and no amniocentesis; spina bifida was detected by ultrasonography near term.

Therefore sensitivity for initial detection of fetal neural tube defects by ultrasonography without amniocentesis at this referral laboratory was 10 of 14 or 71% during 1989. In our experience the incentive to "look harder" appears to be based in part on the abnormal results from the amniocentesis. Current medical practice emphasizes dependency on amniocentesis. In our series, seven patients (cases 5 through 11) with pregnancy ages ranging between 15 and 34 weeks, had isolated neural tube defects detected by ultrasonography before amniocentesis. All these had elevated amniotic fluid AFP levels or positive acetylcholinesterase values, confirming what was already known, and all chromosome study results were normal. Another patient (case 12) with an elevated maternal serum AFP level was found by ultrasonography to have hand deformities as well as encephalocele; fetal chromosome diagnosis was requested. Chromosomes were normal, amniotic fluid AFP level was 5.7 multiples of the mean, and the acetylcholinesterase value was positive. Only the remaining two patients (cases 13 and 14) had elevated maternal serum AFP levels at 18 and 20 weeks' gestation, respectively, and a neural tube defect was detected in each fetus by ultrasonography alone with no amniocentesis, the scenario recommended by Nadel et al.[2]

HCG or β-hCG or hCG β-subunit or hCG + hCG β-subunit?

To the Editors: I wonder whether authors, reviewers, and editors of prestigious obstetric and gynecologic journals are concerned about what has been measured when determinations of choriogonadotropin or its subunits are published.

According to the title and text of one of the latest articles in this respect (Schiff E, Ben-Baruch G, Moran O, et al. Prediction of residual trophoblastic tissue in first-trimester abortions and low levels of human chorionic gonadotropin β-subunit. AM J OBSTET GYNECOL 1990;162:797-801), the determination of human chorionic gonadotropin (hCG) β-subunit was intended. However, the method to which the authors referred is characterized as follows: "The capture antibody . . . binds both intact hCG and its beta-subunit. . . . we used two ^{125}I labeled antibodies. . . . One of these . . . binds intact hCG, the other . . . is specific for the beta-subunit of hCG"[1] and "We calibrated the standards against IRP 75/537,"[1] which contains complete hCG essentially without free β-subunit.[2] Thus by the method Schiff et al. quoted, complete hCG + hCG β-subunit is measured and the result is expressed in terms of IU (IRP 75/537), although "this . . . approach can be adapted to measuring intact hCG and its beta subunit either separately or in combination."[1] Schiff et al., on the other hand, state "The measurement units are according to the second international standard of the International Health Organization." However, this standard, IS 61/6, "is unsuitable for use in all immunoassay systems because of its heterogeneity"[3] or at least is subject for discussion.[4]

In any case, neither IRP 75/537 nor IS 61/6 but IRP 75/551 (or hCG β of the CR series) is appropriate as standard for measurement of hCG β-subunit.[2] In addition, Schiff et al. do not mention whether or in which way they modified the method[1] for measuring not hCG + hCG β-subunit but the β-subunit separately.

Finally, they do not discuss whether or why in the intended prediction of residual trophoblastic tissue, measurement of hCG β-subunit should be advantageous as compared with measurement of hCG or with measurement of hCG + hCG β-subunit. This advantage seems to be rather improbable because the molar ratio of free hCG β-subunit to intact hCG was found to be about 1/100 in the first half of pregnancy.[5, 6]

Reply

To the Editors: We appreciate the comments by Dr. Kuss regarding our article. His concern with respect to the method used is understandable. The method reported by Rattle et al.,[1] to which we referred, can indeed be adapted to the measurement of intact human chorionic gonadotropin and its β-subunit, either separately or in combination. We have again verified with our laboratory that the assay used for all our blood samples specifically tested the β-subunits of human chorionic gonadotropin by the same method (i.e., iodine 125 immunoradiometric assay) involving specific anti-β-subunit monoclonal antibodies.

Simplified urethrocystovaginal suspension for stress urinary incontinence

To the Editors: I am very interested in the article by Varner (Varner RE. Retropubic long-needle suspension procedures for stress urinary incontinence. AM J OBSTET GYNECOL 1990;163:551-7). I described practically the same procedure (Cervicocystovaginopexie simplifiée dans le traitement de l'incontinence urinaire [Simplified cervicocystovaginopexy for stress urinary incontinence] Montpellier Chir 1972;18:191-3). The only difference is the vaginal incision. I used a midline incision and not a transverse incision (Fig. 1, *A* and *B*).

In 1978, Peyreyra reported the blunt retropubic dissection already published in my article.

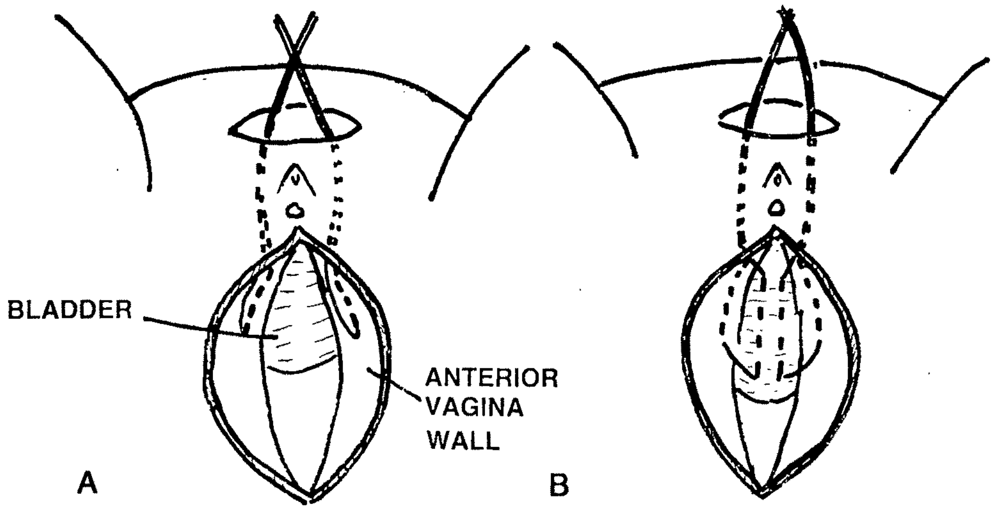

Fig. 1. A, Ureterovaginal suspension. **B,** Ureterocystovaginal suspension.

In 1982, Muzsnai published the same technique with a little modification: He used three sutures placed through the vaginal wall with one bite instead of one suture with several bites as in my procedure.

N. Nghiem Toan, MD
Service de Gynécologie-Obstétrique, Centre Hospitalier de Vichy, Bd Denière, 03200, Vichy, France

Reply

To the Editors: Dr. N. Nghiem Toan has noted two further articles in the French literature that describe procedures that use variations of Dr. A.J. Pereyra's original procedure. These were overlooked as references in my article. I apologize for this. I was able to review Dr. Nghiem-Toan's article with a French translator.

Dr. Nghiem-Toan described a variation of the modified Pereyra procedure that he performed on eight patients with "very nice results for 18 months." He used a single-needle passage from the rectus fascia downward to each side of the bladder neck as was described by Pereyra. Unlike the current Pereyra procedure, he apparently did not penetrate or dissect the space of Retzius from below, but "dissected up to the level of the anterior pubic rami." There was no mention of cystoscopic observation of the anterior bladder to rule out suture perforation, which may be a somewhat common occurrence when the needle is passed without digital guidance. Finally, a vertical vaginal incision was used as was mentioned in the above correspondence.

The procedure described in the August 1990 issue of this JOURNAL is unique only in that it uses parts of several previously described procedures to optimize results without increasing operative time and potential morbidity. The suture-loaded Stamey needle is passed from the vaginal to abdominal fascia through the space of Retzius twice on each side of the bladder neck after incorporation of "paravaginal fascia" in three bites. It is believed that the separate passage of the suture ends, some 1½ cm apart, may further serve to support the bladder neck by thus incorporating pubourethral connective tissue in the support. Cystoscopic observation of the baldder neck to rule out suture perforation and to note proper bladder neck elevation is performed. The transverse vaginal incision is considered to be optimal in that there is no traction on the vaginal suture line. Suture line traction may occur when sutures elevate the vaginal wall lateral to a vertical incision at the level of the bladder neck.

Should routine liver biopsy be done for the definite diagnosis of acute fatty liver of pregnancy?

To the Editors: Dr. Barton et al. presented a case of recurrent acute fatty liver of pregnancy (Barton JR, Sibai BM, Mabie WC, Shanklin DR. Recurrent acute fatty liver of pregnancy. AM J OBSTET GYNECOL 1990;163:534-8) in which they recommended routine liver biopsy for electron microscopy as a means to establish the definite diagnosis of acute fatty liver of pregnancy.

We do not agree with their opinion because of the following reason. Acute fatty liver of pregnancy, which can only be diagnosed histologically with the use of liver specimen in definition, and the hemolysis, elevated liver enzymes, and low platelet count (HELLP) syndrome, which can be diagnosed by noninvasive blood test, share many clinical signs and laboratory abnormalities, especially elevated liver enzyme values and coagulation problems. On the basis of our previous article[1] we believe that one cannot differentiate histologically between acute fatty liver of pregnancy and the HELLP syndrome, and we believe that both diseases are the same disorder. HELLP syndrome has been recognized as a disease that requires immediate delivery to improve clinical outcome.[2-4] Even if the definite diagnosis of acute fatty liver of pregnancy is made for a patient who already shows several signs of HELLP syndrome in addition to no reasonable explanation for the disease excluding HELLP syndrome, treatment may not be altered and one has little to offer a patient in exchange for liver biopsy findings. Further, because our article[1] raises the question of whether acute fatty liver of pregnancy is an independent clinical entity, we do not think that electron microscopy allows us to establish the definite diagnosis of acute fatty liver of pregnancy. Also, we emphasize that liver biopsy is not necessary, at least in clinical practice.

Hisanori Minakami, MD, Tsutomu Takahashi, MD, and Taro Tamada, MD

Reply

To the Editors: We appreciate the interest of Drs. Minakami, Takahashi, and Tamada in our article. We do not suggest routine liver biopsy as a means of establishing the definitive diagnosis of acute fatty liver of pregnancy in all patients for whom this diagnosis is entertained. Rather, if a liver biopsy specimen is obtained for evaluation in these patients, a sample should be properly prepared for electron microscopic analysis as well as routine microscopic examination.

We agree that there is overlap, both clinically and pathologically, between acute fatty liver of pregnancy and hemolysis, elevated liver enzymes, and low platelet count (HELLP) syndrome. A concurrent diagnosis of HELLP syndrome in patients with biopsy-proved acute fatty liver of pregnancy has been reported.[1] But we believe that these syndromes can be distinguished histopathologically.[2] On light microscopy, the vacuolization and necrosis is most prominent in the central zone in acute fatty liver of pregnancy, whereas in HELLP syndrome the necrosis is periportal. On electron microscopy, although fat droplets may be present in hepatocytes from patients with HELLP syndrome, fat droplets are much more numerous in acute fatty liver of pregnancy.

Therefore we continue to believe that liver biopsy is a useful tool to confirm a diagnosis of acute fatty liver of pregnancy. Because of clinical and laboratory variations, this diagnostic procedure is infrequently necessary in the differential diagnosis of HELLP syndrome versus acute fatty liver of pregnancy.[3] Further, the treatment of both conditions remains delivery of the fetus. However, a liver biopsy is useful in distinguishing acute fatty liver of pregnancy from other forms of fulminant hepatic failure that do not require delivery, such as fulminant herpes simplex hepatitis.[4]

We Live Too Short and Die Too Long: How to Achieve and Enjoy Your Natural 100 Year Plus Life Span. Edited by Walter M. Bortz, II. 296 pages. New York, 1991, Bantam Books. $19.95.

ITEMS

Announcements of major meetings and other significant activities must be received at least 8 weeks before the desired month of publication. All announcements carry a charge of $60.00 U.S. per insertion and the fee must accompany the request to publish. Information will be limited to title of meeting, date, place, and an address to obtain further information. Send announcements and payment, payable to this JOURNAL, to Kay G. Goehler, Senior Manuscript Editor, Journal Editing, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318.

The Harvard Medical School, Department of Continuing Education, and The Massachusetts General Hospital, Department of Gynecology, are presenting a postgraduate course in "Vaginal Surgery," directed by David H. Nichols, MD, FACS, FACOG, on October 11, 12, and 13, 1991, at the Ritz-Carlton, Boston, Massachusetts. For information contact: Harvard Medical School, Department of Continuing Education. Tel.: (617) 432-1525.

The Center for Study of Multiple Birth will sponsor the first Twins Days Research Grant Competition and award a $1000 prize to a researcher who proposes the most significant research study. The competition is limited to citizens of the United States and its territories and is open only to qualified researchers who study twins. A requirement for the prize winner is that he or she agree to publish the research in a scientific journal. Interested applicants must submit a typed 250-word abstract of the proposed research to the judging committee, at The Twins Days Festival Committee, Inc., P.O. Box 29, Twinsburg, OH 44087, not later than July 1, 1991. The award will be announced by The Festival Committee and the Center for Study of Multiple Birth on Aug. 3, 1991, at the Twins Days Festival, Twinsburg, Ohio.

Obstetric/Pelvic Imaging, Hands-On Instruction in Diagnostic Ultrasound. Conducted August 12-16, 1991, in Dallas, Texas. For further information call or write Keith Mauney & Associates, Inc., 600 East Las Colinas Blvd., Suite 250, Irving, TX 75039. Tel.: (214) 402-8250.

Third Congress of the International Society of Gynecological Endocrinology, Madonna di Campiglio (Italian Alps), February 9-16, 1992. The presentations will relate to the topic, "The Hormones in Gynecological Endocrinology: From Synthesis to Clinical Implications." For further information contact: Prof. Andrea R. Genazzani, President of I.S.G.E., Department of Obstetrics and Gynecology, University of Modena, Via del Pozzo 71, 41100 Modena, Italy. Tel.: 39 59 360255-360224. Fax: 39 59 371401.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1991 issues from the Publisher, at a cost of $61.00 for domestic, $88.27 for Canada, and $84.00 for international for Vol. 164 (January-June) and Vol. 165 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Subject index*

A

Abnormalities
  Coffee during pregnancy: A reproductive hazard? (Narod et al). 1991;164:1109-14 (Curr. dev.)
  First-trimester transvaginal ultrasonographic screening: incidence of structural anomalies (Rottem) (Letter); (Cullen) (Reply). 1991;164:933
  Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33
  Mild fetal lateral cerebral ventriculomegaly: clinical course and outcome (Bromley et al). 1991;164:863-7
  Screening and detection of congenital malformation (Pitkin). 1991;164:1045-8
ABO blood-group system
  Oral contraceptives and antithrombin III: variations by dosage and ABO blood group (Burkman et al). 1991;164:1453-60
Abortion
  Argon laser versus microscissors for hysteroscopic incision of uterine septa (Candiani et al). 1991;164:87-90
  Attitudes on the ethics of abortion, sex selection, and selective pregnancy termination among health care professionals, ethicists, and clergy likely to encounter such situations (Evans et al). 1991;164:1092-9
  A chill wind blows fresh air (Calvin). 1991;164:706 (Letter)
  Coffee during pregnancy: A reproductive hazard? (Narod et al). 1991;164:1109-14 (Curr. dev.)
  High CA 125 levels and spontaneous abortion (Fuith). 1991;164:236-7 (Letter)
  Residency training and abortion (Rosenfield). 1991;164:1686 (Letter)
  Webster should not affect prenatal diagnosis (Barr et al) (Letter); (Chavkin and Rosenfield) (Reply). 1991;164:706-7
Abortion, threatened
  Rh immune globulin prophylaxis for threatened abortions (Kuller) (Letter); (Dayton et al) (Reply). 1991;164:703-4
Abruptio placentae
  CA 125 levels in abruptio placentae (Witt et al). 1991;164:1225-8
Abscess
  Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Acid-base equilibrium
  Anesthesia and funic acid-base values (Camann) (Letter); (Shyken et al) (Reply). 1991;164:1360-1
Acid-base imbalance
  Neonatal complications at term as related to the degree of umbilical artery acidemia (Winkler et al). 1991;164:637-41
Acidemia; *see* **Acid-base imbalance**
Acoustic stimulation
  Behavioral changes in fetal sheep caused by vibroacoustic stimulation: the effects of cochlear ablation (Parkes et al). 1991;164:1336-43
  Fetal panting: yet another response to the external vibratory acoustic stimulation test (Sherer et al). 1991;164:591-2
  Fetal vibratory acoustic stimulation in twin gestations with simultaneous fetal heart rate monitoring (Sherer et al). 1991;164:1104-6
  Intraabdominal sound levels during vibroacoustic stimulation (Graham et al). 1991;164:1140-4
  Occupational vibration during pregnancy (Abrams and Wasserman). 1991;164:1152 (Letter)
  The significance of amniotic fluid volume during intrapartum fetal acoustic stimulation (Sarno). 1991;164:1100-1
Acquired immunodeficiency syndrome
  Prevalence of acquired immunodeficiency syndrome detected during prenatal care of population of low socioeconomic status (Porto) (Letter); (Barton) (Reply). 1991;164:705-6
Acute renal failure; *see* **Kidney failure, acute**
Acyclovir
  Pharmacokinetics of acyclovir in the term human pregnancy and neonate (Frenkel et al). 1991;164:569-76
Adenofibroma
  Conservative management of breast fibroadenomas (Hindle). 1991;164:1647-51
Adenohypophysitis; *see* **Pituitary diseases**
Adenosine cyclic monophosphate
  Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Adenosine triphosphate
  Mechanisms of asphyxial brain damage, and possible pharmacologic interventions, in the fetus (Espinoza and Parer). 1991;164:1582-91
  Phosphorus 31 magnetic resonance spectroscopy of human placenta and quantitation with perchloric acid extracts (Kay et al). 1991;164:80-7
Adhesions
  Synergistic effect of intraperitoneally administered calcium channel blockade and recombinant tissue plasminogen activator to prevent adhesion formation in an animal model (Dunn et al). 1991;164:1327-30
Adnexa uteri
  A case report of giant cell arteritis of the uterus and adnexa (Summers et al). 1991;164:540-2
  Ovarian neoplasms and the risk of adnexal torsion (Sommerville et al). 1991;164:577-8
Adnexal diseases
  Ultrasonography in the diagnosis of gynecologic disorders (Willson). 1991;164:1064-71
Adnexitis
  The accuracy of clinical findings and laparoscopy in pelvic inflammatory disease (Sellors et al). 1991;164:113-20

---

*January, part 1, 1-240; part 2, 241-466; February, 467-708; March, 709-938; April, 939-1154; May, part 1, 1155-1368; part 2, 1369-1400; June, part 1, 1401-1766; part 2, 1767-1796.

Adnexitis—cont'd
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Chlamydia trachomatis: female pelvic infection (Faro). 1991;164:1767-70
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58
Diagnosis and laparoscopic grading of acute salpingitis (Soper). 1991;164:1370-6
Genital chlamydial infections: epidemiology and reproductive sequelae (Cates and Wasserheit). 1991;164:1771-81
Adrenal cortex hormones
Cocaine in pregnancy: the effect of maternal administration of cocaine on the maternal and fetal pituitary-adrenal axes (Owiny et al). 1991;164:658-63
Dose effects of antenatal corticosteroids for induction of lung maturation in preterm rabbits (Tabor et al). 1991;164:675-81
Adrenergic receptors; *see* **Receptors, adrenergic**
Aged
Clinical implications of screening for cervical cancer under Medicare (Mandelblatt et al). 1991;164:644-51 (Curr. dev.)
Alcohol drinking
Cocaine and the use of alcohol and other drugs during pregnancy (Streissguth et al). 1991;164:1239-43
Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9
Allis test; *see* **Cesarean section**
Alpha 1-antitrypsin
Complexes of activated protein C with α_1-antitrypsin in normal pregnancy and in severe preeclampsia (España et al). 1991;164:1310-6
Alpha fetoproteins
Does unexplained second-trimester (15 to 20 weeks' gestation) maternal serum α-fetoprotein elevation presage adverse perinatal outcome? (Simpson et al). 1991;164:829-36
Follow-up of elevated maternal serum α-fetoprotein levels: Ultrasonography only or amniocentesis? (Whitehead et al). 1991;164:1688-9 (Letter)
Low level of maternal serum α-fetoprotein: its associated anxiety and the effects of genetic counseling (Keenan et al). 1991;164:54-6
Maternal serum α-fetoprotein screening: further consideration of low-volume testing (Strickland et al). 1991;164:711-4 (Clin. opinion)
The roles of ultrasonography and amniocentesis in evaluation of elevated maternal serum α-fetoprotein (Lindfors et al). 1991;164:1571-6
Tables for estimation of individual risks of fetal neural tube and ventral wall defects, incorporating prior probability, maternal serum α-fetoprotein levels, and ultrasonographic examination results (Thornton et al). 1991;164:154-60
Umbilical vein administration of oxytocin for the management of retained placenta: Is it effective? (Huber et al). 1991;164:1216-9
Amenorrhea
Ten-year follow-up of patients with secondary amenorrhea and normal prolactin (Davajan et al). 1991;164:1666-72
The American Board of Obstetrics and Gynecology
New certifications: principal specialty. 1991;164:1692-708
New certifications: subspecialty of Gynecologic Oncology. 1991;164:1711
New certifications: subspecialty of Maternal-Fetal Medicine. 1991;164:1710-1
New certifications: subspecialty of Reproductive Endocrinology. 1991;164:1709-10
American Gynecological and Obstetrical Society
Transactions of the ninth annual meeting of the American Gynecological and Obstetrical Society. 1991;164:939-1071
AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY
A change in the masthead. 1991;164:1 (Editorial)
Summary of analysis of published articles. 1991;164:709-10 (Editorial)
Amino acids
The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation (Bernardini et al). 1991;164:1481-90
Aminoglycosides
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Amniocentesis
Cytomegalovirus infection (Hershey). 1991;164:1687 (Letter)
Follow-up of elevated maternal serum α-fetoprotein levels: Ultrasonography only or amniocentesis? (Whitehead et al). 1991;164:1688-9 (Letter)
The roles of ultrasonography and amniocentesis in evaluation of elevated maternal serum α-fetoprotein (Lindfors et al). 1991;164:1571-6
Amnioinfusion; *see* **Amniotic fluid**
Amnion
Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
Morphologic changes in the human amnion epithelium that accompany labor as seen with scanning and transmission electron microscopy (Sonek et al). 1991;164:1174-80
Regulation of CA 125 production by amnion and WISH cells in culture (Barbati et al). 1991;164:1355-9
Amniotic fluid
Amniotic endothelin increase during pregnancy (Raboni et al). 1991;164:237 (Letter)
Amniotic fluid glucose and intraamniotic infection (Kirshon et al). 1991;164:818-20
Fetal urine output does not influence residual amniotic fluid volume after premature rupture of membranes (Watson et al). 1991;164:64-5
Human amniotic fluid modulation of collagenase production in cultured fibroblasts (Vadillo-Ortega et al). 1991;164:664-8
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Progress in pathogenesis and management of clinical intraamniotic infection (Gibbs and Duff). 1991;164:1317-26 (Curr. dev.)
Questions about prophylactic intrapartum amnioinfusion (Chauhan) (Letter); (Strong) (Reply). 1991;164:1365-6
Rapid intramembranous absorption into the fetal circulation of arginine vasopressin injected intraamniotically (Gilbert et al). 1991;164:1013-20

The significance of amniotic fluid volume during intrapartum fetal acoustic stimulation (Sarno). 1991;164:1100-1
Transplacental, amniotic, urinary, and fetal fluid dynamics during very-large-volume fetal intravenous infusions (Brace and Moore). 1991;164:907-16
Was there really a difference with amnioinfusion? (Goodlin) (Letter); (Owen and Hauth) (Reply). 1991;164:235-6
Amniotic fluid embolism; *see* **Embolism, amniotic fluid**
Analgesia
The effect of sterile water blocks on low back labor pain (Trolle et al). 1991;164:1277-81
Anemia
Anemia and spontaneous preterm birth (Klebanoff et al). 1991;164:59-63
Mechanisms of hemolysis and anemia associated with acute antepartum pyelonephritis (Cox et al). 1991;164:587-90
Anesthesia
Anesthesia and funic acid-base values (Camann) (Letter); (Shyken et al) (Reply). 1991;164:1360-1
Effects of acute hypermagnesemia on the threshold for lidocaine-induced seizures in the rat (Choi et al). 1991;164:693-7
The hemodynamic effects of intubation during nitroglycerin infusion in severe preeclampsia (Longmire et al). 1991;164:551-6
Angiosarcoma; *see* **Hemangiosarcoma**
Angiotensin II
Effect of low-dose aspirin on vascular refractoriness in angiotensin-sensitive primigravid women (Wallenburg et al). 1991;164:1169-73
Animal welfare
The issue of animal rights and human rights (Maharry). 1991;164:1543-8 (Pres. address)
Antepartum testing; *see* **Research design**
Antibiotics
Antimicrobials in the 1990s: expanded options for effective patient care—introduction (Faro). 1991;164:1369
Antimicrobials in the 1990s: expanded options for effective patient care—summary (Faro). 1991;164:1399-400
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
New directions in the diagnosis and therapy of urinary tract infections (Powers). 1991;164:1387-9
Patient costs for prophylaxis and treatment of obstetric and gynecologic surgical infections (Stein). 1991;164:1377-80
Progress in pathogenesis and management of clinical intraamniotic infection (Gibbs and Duff). 1991;164:1317-26 (Curr. dev.)
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
Susceptibility of female pelvic pathogens to oral antibiotic agents in patients who develop postpartum endometritis (Martens et al). 1991;164:1383-6
Antibiotics, lactam
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Antibodies
Antisperm antibodies to sperm surface antigens in women with genital tract infection (Cunningham et al). 1991;164:791-6
Budd-Chiari syndrome, obstetric complications, and antiphospholipid antibodies (Cowchock) (Letter); (Ilan et al) (Reply). 1991;164:235
Intravenous immunoglobulin treatment of recurrent pregnancy loss and antiphospholipid antibodies (Orvieto et al). 1991;164:1687-8 (Letter)
Antibodies, monoclonal
Overexpression of HER-2/*neu* in endometrial cancer is associated with advanced stage disease (Berchuck et al). 1991;164:15-21
Anticonvulsants
Antiepileptic medication in pregnancy: late effects on the children's central nervous system development (van der Pol et al). 1991;164:121-8
Antide
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94
Antiepileptic medication; *see* **Anticonvulsants**
Antigens, neoplasm
Analysis of antigen expression at multiple tumor sites in epithelial ovarian cancer (Rubin et al). 1991;164:558-63
The value of squamous cell carcinoma antigen in patients with locally advanced cervical cancer undergoing neoadjuvant chemotherapy (Scambia et al). 1991;164:631-6
Antigens, surface
Antisperm antibodies to sperm surface antigens in women with genital tract infection (Cunningham et al). 1991;164:791-6
Antigens, tumor-associated, carbohydrate
CA 125 levels in abruptio placentae (Witt et al). 1991;164:1225-8
High CA 125 levels and spontaneous abortion (Fuith). 1991;164:236-7 (Letter)
Regulation of CA 125 production by amnion and WISH cells in culture (Barbati et al). 1991;164:1355-9
Antimicrobials; *see* **Antibiotics**
Antineoplastic agents
The value of squamous cell carcinoma antigen in patients with locally advanced cervical cancer undergoing neoadjuvant chemotherapy (Scambia et al). 1991;164:631-6
Antiphospholipid antibodies; *see* **Antibodies**
Antisperm antibodies; *see* **Antibodies**
Antithrombin III
Oral contraceptives and antithrombin III: variations by dosage and ABO blood group (Burkman et al). 1991;164:1453-60
Anus
Estrogen receptors in the external anal sphincter (Haadem et al). 1991;164:609-10
Anxiety
Low level of maternal serum α-fetoprotein: its associated anxiety and the effects of genetic counseling (Keenan et al). 1991;164:54-6
Aorta
The effects of hormone replacement therapy in normal postmenopausal women: measurements of Doppler-derived parameters of aortic flow (Pines et al). 1991;164:806-12
Apgar score
Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9

Apgar score—cont'd
Umbilical arterial and venous acid-base and blood gas values and the effect of chorioamnionitis on those values in a cohort of preterm infants (Hankins et al). 1991;164:1261-4
Arcuate nucleus
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Arginine vasopressin; *see* **Argipressin**
Argipressin
Rapid intramembranous absorption into the fetal circulation of arginine vasopressin injected intraamniotically (Gilbert et al). 1991;164:1013-20
Argon
Argon laser versus microscissors for hysteroscopic incision of uterine septa (Candiani et al). 1991;164:87-90
Arrhythmia
Continuous electrocardiographic monitoring in hypertensive crises in pregnancy (Naidoo et al). 1991;164:530-3
Ascites
Endometriosis associated with massive ascites and absence of pelvic peritoneum (Williams and Wagaman). 1991;164:45-6
Asphyxia neonatorum
Mechanisms of asphyxial brain damage, and possible pharmacologic interventions, in the fetus (Espinoza and Parer). 1991;164:1582-91
Neonatal complications at term as related to the degree of umbilical artery acidemia (Winkler et al). 1991;164:637-41
Aspirin
Effect of low-dose aspirin on vascular refractoriness in angiotensin-sensitive primigravid women (Wallenburg et al). 1991;164:1169-73
Astrocytes
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Atrial natriuretic factor; *see* **Natriuretic peptides, atrial**
Autoantibodies
The relationship between autoantibodies and intrauterine growth retardation in hypertensive disorders of pregnancy (El-Roeiy et al). 1991;164:1253-61
Autoimmune diseases
Recurrent herpes gestationis with postpartum flare: a case report (Baxi et al). 1991;164:778-80
Azithromycin
Chlamydia trachomatis: female pelvic infection (Faro). 1991;164:1767-70
New treatments for *Chlamydia trachomatis* (Jones). 1991;164:1789-93
The role of azalide antibiotics in the treatment of chlamydia (Johnson). 1991;164:1794-6

B

Backache
The effect of sterile water blocks on low back labor pain (Trolle et al). 1991;164:1277-81
Bacterial infection; *see* **Infection**
Bacteroides fragilis
Phospholipase C activity in microorganisms associated with reproductive tract infection (McGregor et al). 1991;164:682-6
Bacterologic techniques
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
Behavior, animal
Behavioral changes in fetal sheep caused by vibroacoustic stimulation: the effects of cochlear ablation (Parkes et al). 1991;164:1336-43
Beta-endorphin
Enhancement of germ tube formation in *Candida albicans* by β-endorphin (Witkin and Kalo-Klein). 1991;164:917-20
Beta-hCG; *see* **Gonadotropins, chorionic**
Beta-lactam antibiotics; *see* **Antibiotics, lactam**
Beta-sympathomimetics; *see* **Sympathomimetics**
Biological assay
Recurrent failure of in vitro fertilization: role of the hemizona assay in the sequential diagnosis of specific sperm-oocyte defects (Oehninger et al). 1991;164:1210-5
Biophysical profile; *see* **Fetal monitoring**
Biopsy
The accuracy of clinical findings and laparoscopy in pelvic inflammatory disease (Sellors et al). 1991;164:113-20
Should routine liver biopsy be done for the definite diagnosis of acute fatty liver of pregnancy? (Minakami et al) (Letter); (Barton and Sibai) (Reply). 1991;164:1690-1
Birth weight
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
The biologic and social consequences of perinatal cocaine use in an inner-city population: results of an anonymous cross-sectional study (McCalla et al). 1991;164:625-30
Birth weights of infants of black and white mothers without pregnancy complications (Hulsey et al). 1991;164:1299-302
Coffee during pregnancy: A reproductive hazard? (Narod et al). 1991;164:1109-14 (Curr. dev.)
Cross-sectional analysis of triplet birth weight (Jones et al). 1991;164:135-40
Gestational age in relation to marine *n*-3 fatty acids in maternal erythrocytes: a study of women in the Faroe Islands and Denmark (Olsen et al). 1991;164:1203-9
Maternal postprandial glucose levels and infant birth weight: the Diabetes in Early Pregnancy Study (Jovanovic-Peterson et al). 1991;164:103-11
Postterm infants: Too big or too small? (McLean et al). 1991;164:619-24
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42
Blacks
Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9
Bleeding; *see* **Hemorrhage**
Blood circulation
Effect of intravenous cocaine on uterine blood flow in the gravid baboon (Morgan et al). 1991;164:1021-30
Blood coagulation; *see* **Coagulation**
Blood flow velocity
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63

The effects of hormone replacement therapy in normal postmenopausal women: measurements of Doppler-derived parameters of aortic flow (Pines et al). 1991;164:806-12
The effects of indomethacin and a β-sympathomimetic agent on the fetal ductus arteriosus during treatment of premature labor: a randomized double-blind study (Eronen et al). 1991;164:141-6
Evaluation of changes in umbilical blood flow in the fetal lamb by Doppler waveform analysis (Schmidt et al). 1991;164:1118-26
Flow velocity waveforms of the fetal circulation preceding fetal death in a case of lupus anticoagulant (Mari and Wasserstrum). 1991;164:776-8
Transvaginal color Doppler imaging in the assessment of uteroplacental blood flow in the normal first-trimester pregnancy (Jaffe and Warsof). 1991;164:781-5
Umbilical artery blood flow velocity waveforms during variable decelerations of the fetal heart rate (Weiss et al). 1991;164:534-40

Blood gas analysis
Anesthesia and funic acid-base values (Camann) (Letter); (Shyken et al) (Reply). 1991;164:1360-1
Umbilical arterial and venous acid-base and blood gas values and the effect of chorioamnionitis on those values in a cohort of preterm infants (Hankins et al). 1991;164:1261-4

Blood platelets
Quantitative and qualitative platelet abnormalities during pregnancy (How et al). 1991;164:92-8

Blood pressure monitors
Blood pressure self-monitoring during pregnancy: practical considerations (Zuspan and Rayburn). 1991;164:2-6 (Clin. opinion)

Blood transfusion, intrauterine
Intrauterine transfusion treatment of nonimmune hydrops fetalis secondary to human parvovirus B19 infection (Sahakian et al). 1991;164:1090-1

Blood vessels
Endothelin and neuropeptide Y are vasoconstrictors in human uterine blood vessels (Fried and Samuelson). 1991;164:1330-6

Blood volume, animal
The effect of volume expansion on placental blood flow in awake hypovolemic rats in late pregnancy (Boekkooi et al). 1991;164:921-6

Body height
Effect of subject height on the result for the fifty-gram oral glucose tolerance test (Phillipou). 1991;164:698 (Letter)

Body mass index
The clinical utility of maternal body mass index in pregnancy (Wolfe et al). 1991;164:1306-10

Body temperature
Association between hypothermia and mortality rate of premature infants—revisited (Hazan et al). 1991;164:111-2
Factors influencing the initiation of nonshivering thermogenesis (Gunn et al). 1991;164:210-7

Body weight
The clinical utility of maternal body mass index in pregnancy (Wolfe et al). 1991;164:1306-10

Bone marrow transplantation
Transplantation of fetal cells (Crombleholme et al). 1991;164:218-30 (Curr. dev.)

Books
Books received. 1991;164:937, 1367, 1712-3

Brain injuries
Mechanisms of asphyxial brain damage, and possible pharmacologic interventions, in the fetus (Espinoza and Parer). 1991;164:1582-91

Breast
The mammary stimulation test—A predictor of preterm delivery? (Eden et al). 1991;164:1409-19

Breast neoplasms
Conservative management of breast fibroadenomas (Hindle). 1991;164:1647-51

Brewer, J.
A change in the masthead. 1991;164:1 (Editorial)

Budd-Chiari syndrome; *see* **Hepatic vein thrombosis**

C

C-myc genes; *see* **Genes, myc**

CA 125; *see* **Antigens, tumor-associated, carbohydrate**

Caffeine
Coffee during pregnancy: A reproductive hazard? (Narod et al). 1991;164:1109-14 (Curr. dev.)

Calcium
Calcium-regulating hormones and osteocalcin levels during pregnancy: a longitudinal study (Seki et al). 1991;164:1248-52
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50
Passive membrane properties and inward calcium current of human uterine smooth muscle cells (Young et al). 1991;164:1132-9

Calcium channel agonists
Passive membrane properties and inward calcium current of human uterine smooth muscle cells (Young et al). 1991;164:1132-9

Calcium channel blockers
Periovulatory calcium channel blockade enhances reproductive performance in an animal model for endometriosis-associated subfertility (Steinleitner et al). 1991;164:949-52
Synergistic effect of intraperitoneally administered calcium channel blockade and recombinant tissue plasminogen activator to prevent adhesion formation in an animal model (Dunn et al). 1991;164:1327-30

Candida albicans
Enhancement of germ tube formation in *Candida albicans* by β-endorphin (Witkin and Kalo-Klein). 1991;164:917-20
Regulation of the immune response to *Candida albicans* by monocytes and progesterone (Kalo-Klein and Witkin). 1991;164:1351-4

Carcinoma, squamous cell
Stage IB squamous cell cancer of the cervix: clinicopathologic features related to survival (Hopkins and Morley). 1991;164:1520-9
Trends in the operative management of invasive squamous carcinoma of the vulva at Indiana University, 1974 to 1988 (Sutton et al). 1991;164:1472-81
The value of squamous cell carcinoma antigen in patients with locally advanced cervical cancer undergoing neoadjuvant chemotherapy (Scambia et al). 1991;164:631-6

Carcinoma staging; *see* **Neoplasm staging**

Cardiac function tests; *see* **Heart function tests**

Cardiac output, animal
The effect of volume expansion on placental blood flow in

Cardiac output, animal—cont'd
awake hypovolemic rats in late pregnancy (Boekkooi et al). 1991;164:921-6
Cardinal ligament; *see* **Ligaments**
Cardiopulmonary bypass
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Kool). 1991;164:701-2 (Letter)
Cardiotocography
The contributions of the nurse and the machine in home uterine activity monitoring systems (Merkatz and Merkatz). 1991;164:1159-62 (Clin. opinion)
Cardiovascular diseases
Reduction of cardiovascular disease–related mortality among postmenopausal women who use hormones: evidence from a national cohort (Wolf et al). 1991;164:489-94
Carnitine
The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation (Bernardini et al). 1991;164:1481-90
Carriers, genetic, detection; *see* **Heterozygote detection**
Catechol methyltransferase
Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
Catecholamines
Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7
Factors influencing the initiation of nonshivering thermogenesis (Gunn et al). 1991;164:210-7
Cefoxitin
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
Ceftriaxone
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
Cell adhesion molecules
Cell adhesion molecules and the regulation of development (Cunningham). 1991;164:939-48
Cell-mediated immunity; *see* **Immunity, cellular**
Cells, cultured
Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Central Association of Obstetricians and Gynecologists
Transactions of the fifty-eighth annual meeting of the Central Association of Obstetricians and Gynecologists. 1991;164:1401-542
Central nervous system
Antiepileptic medication in pregnancy: late effects on the children's central nervous system development (van der Pol et al). 1991;164:121-8
The role of the transcerebellar view in the detection of fetal central nervous system anomaly (Hill et al). 1991;164:1220-4
Transvaginal ultrasonographic definition of the central nervous system in the first and early second trimesters (Timor-Tritsch et al). 1991;164:497-503
Cerclage; *see* **Cervix incompetence**
Cerebellum
The role of the transcerebellar view in the detection of fetal central nervous system anomaly (Hill et al). 1991;164:1220-4
Cerebral aneurysm
Evaluation of an aneurysm of the vein of Galen in utero by pulsed and color Doppler ultrasonography (Ishimatsu et al). 1991;164:743-4
Cerebral palsy
Neonatal complications at term as related to the degree of umbilical artery acidemia (Winkler et al). 1991;164:637-41
Cerebral veins
Evaluation of an aneurysm of the vein of Galen in utero by pulsed and color Doppler ultrasonography (Ishimatsu et al). 1991;164:743-4
Cervical cancer; *see* **Cervix neoplasms**
Cervical dilation; *see* **Labor**
Cervical neoplasia; *see* **Cervix neoplasms**
Cervicitis
Chlamydia trachomatis: female pelvic infection (Faro). 1991;164:1767-70
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
Cervix dysplasia
The increased frequency of cervical dysplasia-neoplasia in women infected with the human immunodeficiency virus is related to the degree of immunosuppression (Schäfer et al). 1991;164:593-9
Cervix incompetence
Dilatation despite cervical cerclage: a diagnostic pitfall (Jacquemyn and Buytaert). 1991;164:1686-7 (Letter)
Transabdominal cervicoisthmic cerclage: a reappraisal 25 years after its introduction (Novy). 1991;164:1635-42
Cervix mucous
The importance of the postcoital test (Check) (Letter); (Grimes and Griffith) (Reply). 1991;164:932-3
Cervix neoplasms
Clinical implications of screening for cervical cancer under Medicare (Mandelblatt et al). 1991;164:644-51 (Curr. dev.)
Dissection of the cardinal ligament in radical hysterectomy for cervical cancer with emphasis on the lateral ligament (Yabuki et al). 1991;164:7-14 (Clin. opinion)
The increased frequency of cervical dysplasia-neoplasia in women infected with the human immunodeficiency virus is related to the degree of immunosuppression (Schäfer et al). 1991;164:593-9
Laparoscopic pelvic lymphadenectomy in the staging of early carcinoma of the cervix (Querleu et al). 1991;164:579-81
Should cervical cytologic testing be augmented by cervicography or human papillomavirus deoxyribonucleic acid detection? (Reid et al). 1991;164:1461-71
Stage IB squamous cell cancer of the cervix: clinicopatho-

logic features related to survival (Hopkins and Morley). 1991;164:1520-9
The value of squamous cell carcinoma antigen in patients with locally advanced cervical cancer undergoing neoadjuvant chemotherapy (Scambia et al). 1991;164:631-6

Cervix uteri
Dilatation despite cervical cerclage: a diagnostic pitfall (Jacquemyn and Buytaert). 1991;164:1686-7 (Letter)
A new model for objective assessment of cervical ripening: the effect of prostaglandin E_2 and prelabor contractility (Takahashi et al). 1991;164:1115-8
Should cervical cytologic testing be augmented by cervicography or human papillomavirus deoxyribonucleic acid detection? (Reid et al). 1991;164:1461-71
The use of the Cytobrush cervical sampler in patients with cervical stenosis (Hoffman et al). 1991;164:52-3

Cesarean section
The Allis test for easy cesarean delivery (Finan et al). 1991;164:772-5
Early neonatal mortality and cesarean delivery in Mexico City (Bobadilla and Walker). 1991;164:22-8
Low-risk cesarean section prophylaxis issue still unsettled (Pearlman et al) (Letter); (Ehrenkranz et al) (Reply). 1991;164:232-4
Susceptibility of female pelvic pathogens to oral antibiotic agents in patients who develop postpartum endometritis (Martens et al). 1991;164:1383-6

Chemotherapy, antineoplastic; *see* **Antineoplastic agents**

Child development
Antiepileptic medication in pregnancy: late effects on the children's central nervous system development (van der Pol et al). 1991;164:121-8

Chlamydia infections
Chlamydia trachomatis: female pelvic infection (Faro). 1991;164:1767-70
Chlamydia trachomatis infection during pregnancy (McGregor and French). 1991;164:1782-9
Chlamydial infection and pregnancy outcome (Forster et al) (Letter); (Ryan) (Reply). 1991;164:234
Genital chlamydial infections: epidemiology and reproductive sequelae (Cates and Wasserheit). 1991;164:1771-81
New treatments for *Chlamydia trachomatis* (Jones). 1991;164:1789-93
The role of azalide antibiotics in the treatment of chlamydia (Johnson). 1991;164:1794-6

Chlamydia trachomatis
Chlamydia trachomatis: female pelvic infection (Faro). 1991;164:1767-70
Chlamydia trachomatis infection during pregnancy (McGregor and French). 1991;164:1782-9
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Cost-effectiveness of prenatal testing for *Chlamydia trachomatis* (Nettleman and Bell). 1991;164:1289-94
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
Intraamniotic detection of *Chlamydia trachomatis* deoxyribonucleic acid sequences by polymerase chain reaction (Pao et al). 1991;164:1295-9
New treatments for *Chlamydia trachomatis* (Jones). 1991;164:1789-93
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
The role of azalide antibiotics in the treatment of chlamydia (Johnson). 1991;164:1794-6

Cholesterol
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94

Chorioamnionitis
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Umbilical arterial and venous acid-base and blood gas values and the effect of chorioamnionitis on those values in a cohort of preterm infants (Hankins et al). 1991;164:1261-4

Choriocarcinoma
Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Prognostic factors in gestational trophoblastic tumors: a proposed new scoring system based on multivariate analysis (Lurain et al). 1991;164:611-6

Chorion
Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
The clinical implications of subchorionic placental lucencies (Katz et al). 1991;164:99-100
Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50

Choristoma
Endosalpingosis as a cause of chronic pelvic pain (Davies and Maclin). 1991;164:495-6

Choroid plexus
Fetal choroid plexus cysts in the second trimester of pregnancy: a cause for concern (Platt et al). 1991;164:1652-6

Chromatography, high pressure liquid
Decreased levels of polyunsaturated fatty acids in preeclampsia (Wang et al). 1991;164:812-8

Chromosomes
Frontothalamic measurement in the second trimester of pregnancy (Crade et al). 1991;164:704-5 (Letter)

Cisplatin
Toxicities in rats with free versus liposomal encapsulated cisplatin (Potkul et al). 1991;164:652-8

Climacteric
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8

Clindamycin
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58

Clinical opinion
Clinical opinion. 1991;164:2-14, 467-76, 711-21, 1072-83, 1155-62

Clostridium histolyticum collagenase
Human amniotic fluid modulation of collagenase production in cultured fibroblasts (Vadillo-Ortega et al). 1991;164:664-8

Clothing
Panty hose–pants disease (Turner). 1991;164:1366 (Letter)
CMV infection; *see* **Cytomegaloviruses**
Coagulation
Coagulation changes on natural estrogens (Coope). 1991;164:236 (Letter)
Cocaine
The biologic and social consequences of perinatal cocaine use in an inner-city population: results of an anonymous cross-sectional study (McCalla et al). 1991;164:625-30
Cocaine and the use of alcohol and other drugs during pregnancy (Streissguth et al). 1991;164:1239-43
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7
Cocaine in pregnancy: the effect of maternal administration of cocaine on the maternal and fetal pituitary-adrenal axes (Owiny et al). 1991;164:658-63
Effect of intravenous cocaine on uterine blood flow in the gravid baboon (Morgan et al). 1991;164:1021-30
Cochlea
Behavioral changes in fetal sheep caused by vibroacoustic stimulation: the effects of cochlear ablation (Parkes et al). 1991;164:1336-43
Coffee
Coffee during pregnancy: A reproductive hazard? (Narod et al). 1991;164:1109-14 (Curr. dev.)
Colchicine
Regulation of CA 125 production by amnion and WISH cells in culture (Barbati et al). 1991;164:1355-9
Collagenase; *see* **Clostridium histolyticum collagenase**
Color Doppler ultrasonography; *see* **Ultrasonography**
Colporrhaphy; *see* **Vagina**
Colposcopy
Cervical findings in rape victims (Slaughter and Brown). 1991;164:528-9
Computerized digital colposcopy (Mikhail and Romney) (Letter); (Crisp et al) (Reply). 1991;164:1364-5
Compliance
Dose effects of antenatal corticosteroids for induction of lung maturation in preterm rabbits (Tabor et al). 1991;164:675-81
A risk-benefit analysis of elective bilateral oophorectomy: effect of changes in compliance with estrogen therapy on outcome (Speroff et al). 1991;164:165-74 (Curr. dev.)
Computerized digital colposcopy; *see* **Colposcopy**
Condyloma acuminata
Therapy of persistent human papillomavirus disease with two different interferon species (Gall et al). 1991;164:130-4
Congenital defects; *see* **Abnormalities**
Congestive heart failure; *see* **Heart failure, congestive**
Conjunctivitis
Chlamydia trachomatis infection during pregnancy (McGregor and French). 1991;164:1782-9
Consensus interferon; *see* **Interferons**
Contraceptive devices
A comparison of flurbiprofen, tranexamic acid, and a levonorgestrel-releasing intrauterine contraceptive device in the treatment of idiopathic menorrhagia (Milsom et al). 1991;164:879-83
Contraceptives, oral
The effect of tetracycline on levels of oral contraceptives (Murphy et al). 1991;164:28-33
Oral contraceptives and antithrombin III: variations by dosage and ABO blood group (Burkman et al). 1991;164:1453-60
Ovarian response in superovulated cycles after suppression with oral contraceptive steroids (Burry et al). 1991;164:1592-6
Cord blood; *see* **Fetal blood**
Cordocentesis; *see* **Fetal blood**
Corpus luteum hormones
The induction of premature luteolysis in normal women—follicular phase luteinizing hormone secretion and corpus luteum function in the subsequent cycle (Soules et al). 1991;164:989-96
Corpus luteum regression
The induction of premature luteolysis in normal women—follicular phase luteinizing hormone secretion and corpus luteum function in the subsequent cycle (Soules et al). 1991;164:989-96
Corrections
Definition of fetal asphyxia (Clark) (Letter); (Johnson and Richards) (Reply) (1990;163:1364). 1991;164:1359
Morphologic study of changes of collagenous tissue in the amnion and cervix during prostaglandin-induced abortion and delivery (Manabe and Yoshida) (1990;163:52-6). 1991;164:707
Risk factors for perinatal group B streptococcal disease after amniotic fluid colonization (Silver et al.) (1990;163:19-25). 1991;164:1359
Correspondence
Letters. 1991;164:231-7, 698-707, 931-6, 1151-3, 1360-6, 1686-91
Corticosteroids; *see* **Adrenal cortex hormones**
Cost benefit analysis
Cost-effectiveness of prenatal testing for *Chlamydia trachomatis* (Nettleman and Bell). 1991;164:1289-94
Glucose challenge testing in pregnancy (Neilson et al). 1991;164:1673-9
Patient costs for prophylaxis and treatment of obstetric and gynecologic surgical infections (Stein). 1991;164:1377-80
Should cervical cytologic testing be augmented by cervicography or human papillomavirus deoxyribonucleic acid detection? (Reid et al). 1991;164:1461-71
Ultrasonography in obstetrics and gynecology: the state of the art in 1990—panel discussion. 1991;164:1044
Cost effectiveness; *see* **Cost benefit analysis**
Creatinine
Suture entrapment and secondary ureteral obstruction (Stanhope et al). 1991;164:1513-9
Cross-sectional studies
The biologic and social consequences of perinatal cocaine use in an inner-city population: results of an anonymous cross-sectional study (McCalla et al). 1991;164:625-30
Cross-sectional analysis of triplet birth weight (Jones et al). 1991;164:135-40
Culture media
Regulation of CA 125 production by amnion and WISH cells in culture (Barbati et al). 1991;164:1355-9
Current development
Current development. 1991;164:165-74, 218-30, 644-51, 888-95, 1109-14, 1317-26
Cyclic adenosine monophosphate; *see* **Adenosine cyclic monophosphate**
Cyproterone
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8

Cystic fibrosis
Carrier screening for cystic fibrosis: implications for obstetric and gynecologic practice (Elias et al). 1991;164:1077-83 (Clin. opinion)

Cytokines
Serum interleukin-6 levels correlate with disease status in patients with epithelial ovarian cancer (Berek et al). 1991;164:1038-43

Cytology
Cervical human papillomavirus deoxyribonucleic acid and cytologic evaluations in gynecologic outpatients (Nieminen et al). 1991;164:1265-9
The use of the Cytobrush cervical sampler in patients with cervical stenosis (Hoffman et al). 1991;164:52-3

Cytomegaloviruses
Cytomegalovirus infection (Hershey). 1991;164:1687 (Letter)

D

Danazol
Hormonal inhibition of the endometrium for resectoscopic endometrial ablation (Brooks et al). 1991;164:1601-8
Metabolic effects of danazol (Williams) (Letter); (Seifer) (Reply). 1991;164:933-4

Deceleration
Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9

Decision making
Cost-effectiveness of prenatal testing for *Chlamydia trachomatis* (Nettleman and Bell). 1991;164:1289-94
Vaginal birth after cesarean section: the impact of patient resistance to a trial of labor (Joseph et al). 1991;164:1441-7

Deformities; *see* **Abnormalities**

Delivery
Epidemiologic characteristics of preterm delivery: etiologic heterogeneity (Savitz et al). 1991;164:467-71 (Clin. opinion)
Fetal-neonatal thrombocytopenia: Mode of delivery? (Levy) (Letter); (Burrows and Kelton) (Reply). 1991;164:1362-3
Incidence of genital herpes simplex virus at the time of delivery in women with known risk factors (Catalano et al). 1991;164:1303-6
Questions about prophylactic intrapartum amnioinfusion (Chauhan) (Letter); (Strong) (Reply). 1991;164:1365-6

Delivery of health care
Winter hath hope of spring (Malinak). 1991;164:1401-8 (Pres. address)

Deoxyribonucleic acid; *see* **DNA**

Diabetes in pregnancy; *see* **Pregnancy in diabetes**

Diabetes insipidus
Transient postpartum diabetes insipidus (Raziel et al). 1991;164:616-8

Diabetes mellitus, insulin dependent
Metabolic effects of danazol (Williams) (Letter); (Seifer) (Reply). 1991;164:933-4

Diabetic mothers; *see* **Pregnancy in diabetes**

Diagnostic errors
Preeclampsia as the great imposter (Goodlin). 1991;164:1577-81

Diagnostic tests
The accuracy of clinical findings and laparoscopy in pelvic inflammatory disease (Sellors et al). 1991;164:113-20
Comparative efficacy of umbilical arterial Doppler indices for predicting adverse perinatal outcome (Maulik et al). 1991;164:1434-40

Diastole
Diastolic circulatory dynamics in the presence of elevated placental resistance and retrograde diastolic flow in the umbilical artery: a Doppler echographic study in lambs (Fouron et al). 1991;164:195-203

Diet
Gestational age in relation to marine n-3 fatty acids in maternal erythrocytes: a study of women in the Faroe Islands and Denmark (Olsen et al). 1991;164:1203-9

Dihydralazine
Management of severe preeclampsia detected in early labor by prostaglandin A_1 or dihydralazine infusions (Toppozada et al). 1991;164:1229-32

Dilatation
Dilatation despite cervical cerclage: a diagnostic pitfall (Jacquemyn and Buytaert). 1991;164:1686-7 (Letter)

Dinoprostone
A new model for objective assessment of cervical ripening: the effect of prostaglandin E_2 and prelabor contractility (Takahashi et al). 1991;164:1115-8

DNA
Intraamniotic detection of *Chlamydia trachomatis* deoxyribonucleic acid sequences by polymerase chain reaction (Pao et al). 1991;164:1295-9
Prenatal diagnosis of myotonic muscular dystrophy with linked deoxyribonucleic acid probes (Milunsky et al). 1991;164:751-5

DNA gyrase
Antimicrobials in the 1990s: expanded options for effective patient care—summary (Faro). 1991;164:1399-400

DNA probes
Prenatal diagnosis of myotonic muscular dystrophy with linked deoxyribonucleic acid probes (Milunsky et al). 1991;164:751-5

DNA probes, HPV
Cervical human papillomavirus deoxyribonucleic acid and cytologic evaluations in gynecologic outpatients (Nieminen et al). 1991;164:1265-9
Should cervical cytologic testing be augmented by cervicography or human papillomavirus deoxyribonucleic acid detection? (Reid et al). 1991;164:1461-71

Doppler echocardiography; *see* **Echocardiography, Doppler**

Doppler ultrasonography; *see* **Ultrasonography**; **Ultrasonography, prenatal**

Doppler velocimeters; *see* **Flowmeters**

Down regulation, animal
Comparison of pulsatile and continuous ritodrine administration: effects on uterine contractility and β-adrenergic receptor cascade (Caritis et al). 1991;164:1005-12

Down's syndrome
The transverse cerebellar diameter in the second trimester is unaffected by Down syndrome (Hill et al). 1991;164:101-3

Doxycycline
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6

Doxycycline—cont'd
The role of azalide antibiotics in the treatment of chlamydia (Johnson). 1991;164:1794-6
Drug abuse; *see* **Substance abuse**
Ductus arteriosus
The effects of indomethacin and a β-sympathomimetic agent on the fetal ductus arteriosus during treatment of premature labor: a randomized double-blind study (Eronen et al). 1991;164:141-6
Dyspareunia
Vulvar vestibulitis: prevalence and historic features in a general gynecologic practice population (Goetsch). 1991;164:1609-16
Dystocia
The Allis test for easy cesarean delivery (Finan et al). 1991;164:772-5

E

Echocardiography
Cardiac function in fetuses of type I diabetic mothers (Rizzo et al). 1991;164:837-43
Echocardiography, Doppler
Cardiac function in fetuses of type I diabetic mothers (Rizzo et al). 1991;164:837-43
The effects of hormone replacement therapy in normal postmenopausal women: measurements of Doppler-derived parameters of aortic flow (Pines et al). 1991;164:806-12
Evaluation of changes in umbilical blood flow in the fetal lamb by Doppler waveform analysis (Schmidt et al). 1991;164:1118-26
Ectopic pregnancy; *see* **Pregnancy, ectopic**
Ectopic tissue; *see* **Choristoma**
Edema
The N-terminal and C-terminal portions of the atrial natriuretic factor prohormone increase during preeclampsia (Merkouris et al). 1991;164:1197-202
Editorials
Editorials. 1991;164:1, 709-10
Editors
A change in the masthead. 1991;164:1 (Editorial)
Elderly; *see* **Aged**
Electrocardiography
Continuous electrocardiographic monitoring in hypertensive crises in pregnancy (Naidoo et al). 1991;164:530-3
The intrauterine probe electrode (Strong et al). 1991;164:1233-4
Electrodes
The intrauterine probe electrode (Strong et al). 1991;164:1233-4
Electron microscopy, transmission; *see* **Microscopy, electron**
Electrophysiology
Characterization of sodium channels in cultured human uterine smooth muscle cells (Young and Herndon-Smith). 1991;164:175-81
Passive membrane properties and inward calcium current of human uterine smooth muscle cells (Young et al). 1991;164:1132-9
Embolism
Pregnancy-related mortality in New York City, 1980 to 1984: causes of death and associated risk factors (Syverson et al). 1991;164:603-8
Embolism, amniotic fluid
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Kool). 1991;164:701-2 (Letter)
Embryo development; *see* **Fetal development**
Embryo transfer
Heterotopic pregnancies after in vitro fertilization and embryo transfer (Rizk et al). 1991;164:161-4
Embryoscopy; *see* **Endoscopy**
Endodermal sinus tumor; *see* **Mesonephroma**
Endometrial cancer; *see* **Uterine neoplasms**
Endometriosis
Endometriosis associated with massive ascites and absence of pelvic peritoneum (Williams and Wagaman). 1991;164:45-6
Macrophage-conditioned media enhance endometrial stromal cell proliferation in vitro (Olive et al). 1991;164:953-8
Periovulatory calcium channel blockade enhances reproductive performance in an animal model for endometriosis-associated subfertility (Steinleitner et al). 1991;164:949-52
c-*myc* Protooncogene polypeptide expression in endometriosis (Schenken et al). 1991;164:1031-7
The use of potassium-titanyl-phosphate laser for laparoscopic removal of ovarian endometrioma (Marrs). 1991;164:1622-8
Endometriosis, animal
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94
Endometritis
Genital chlamydial infections: epidemiology and reproductive sequelae (Cates and Wasserheit). 1991;164:1771-81
Susceptibility of female pelvic pathogens to oral antibiotic agents in patients who develop postpartum endometritis (Martens et al). 1991;164:1383-6
Endometrium
Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50
Endometrial thickness as measured by endovaginal ultrasonography for identifying endometrial abnormality (Granberg et al). 1991;164:47-52
Hormonal inhibition of the endometrium for resectoscopic endometrial ablation (Brooks et al). 1991;164:1601-8
Endometrium, animal
Macrophage-conditioned media enhance endometrial stromal cell proliferation in vitro (Olive et al). 1991;164:953-8
Endosalpingosis; *see* **Choristoma**
Endoscopy
Embryoscopy: old technique new for the 1990s? (Ghirardini) (Letter); (Cullen et al) (Reply). 1991:164:1361-2
Endoscopic sclerotherapy in extrahepatic portal hypertension in pregnancy (Pauzner et al). 1991;164:152-3
Endoscopy, uterine; *see* **Hysteroscopy**
Endothelins
Amniotic endothelin increase during pregnancy (Raboni et al). 1991;164:237 (Letter)
Endothelin and neuropeptide Y are vasoconstrictors in human uterine blood vessels (Fried and Samuelson). 1991;164:1330-6
Human placenta expresses endothelin gene and corresponding protein is excreted in urine in increasing

amounts during normal pregnancy (Benigni et al). 1991;164:844-8

Endothelium
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50

Endothelium-derived relaxing factor
The action of nitric oxide in the perfused human fetal-placental circulation (Myatt et al). 1991;164:687-92
Endothelial-derived relaxing factor released by endothelial cells of human umbilical vessels and its impairment in pregnancy-induced hypertension (Pinto et al). 1991;164:507-13

Endotracheal intubation; *see* **Intubation, intratracheal**

Epidermal growth factor receptors; *see* **Receptors, epidermal growth factor-urogastrone**

Epidermal growth factor-urogastrone
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. I. Correlation of receptor expression with prognostic factors in patients with ovarian cancer (Berchuck et al). 1991;164:669-74
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. II. Relationship between receptor expression and response to epidermal growth factor (Rodriguez et al). 1991;164:745-50

Epilepsy
Antiepileptic medication in pregnancy: late effects on the children's central nervous system development (van der Pol et al). 1991;164:121-8

Episiotomy
Pelvic muscles and episiotomy (Cosner et al) (Letter); (Thorp and Bowes) (Reply). 1991;164:936

Epithelium
Endosalpingosis as a cause of chronic pelvic pain (Davies and Maclin). 1991;164:495-6
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. I. Correlation of receptor expression with prognostic factors in patients with ovarian cancer (Berchuck et al). 1991;164:669-74
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. II. Relationship between receptor expression and response to epidermal growth factor (Rodriguez et al). 1991;164:745-50
Morphologic changes in the human amnion epithelium that accompany labor as seen with scanning and transmission electron microscopy (Sonek et al). 1991;164:1174-80

Erythrocytes
Gestational age in relation to marine *n*-3 fatty acids in maternal erythrocytes: a study of women in the Faroe Islands and Denmark (Olsen et al). 1991;164:1203-9

Erythromycin
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42

Estradiol
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8

Estradiol receptors; *see* **Receptors, estradiol**

Estrogen receptors; *see* **Receptors, estrogen**

Estrogen replacement therapy
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8
Coagulation changes on natural estrogens (Coope) 1991;164:236 (Letter)
The effects of hormone replacement therapy in normal postmenopausal women: measurements of Doppler-derived parameters of aortic flow (Pines et al). 1991;164:806-12
Reduction of cardiovascular disease–related mortality among postmenopausal women who use hormones: evidence from a national cohort (Wolf et al). 1991;164:489-94
A risk-benefit analysis of elective bilateral oophorectomy: effect of changes in compliance with estrogen therapy on outcome (Speroff et al). 1991;164:165-74 (Curr. dev.)
Vasoactive intestinal polypeptide loses its ability to increase vaginal blood flow after menopause (Palle et al). 1991;164:556-8

Estrogens
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Macrophage-conditioned media enhance endometrial stromal cell proliferation in vitro (Olive et al). 1991;164:953-8
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94

Ethics, medical
Residency training and abortion (Rosenfield). 1991;164:1686 (Letter)

Ethics, professional
Attitudes on the ethics of abortion, sex selection, and selective pregnancy termination among health care professionals, ethicists, and clergy likely to encounter such situations (Evans et al). 1991;164:1092-9

Ethinyl estradiol
The effect of tetracycline on levels of oral contraceptives (Murphy et al). 1991;164:28-33
Oral contraceptives and antithrombin III: variations by dosage and ABO blood group (Burkman et al). 1991;164:1453-60

Exomphalos; *see* **Hernia, umbilical**

F

Fallopian tube diseases
Endosalpingosis as a cause of chronic pelvic pain (Davies and Maclin). 1991;164:495-6

Fallopian tube patency tests
Hysterosalpingography with color Doppler ultrasonography (Peters and Coulam). 1991;164:1530-4

Fascia lata, transplantation
Fertility retention in the patient with genital prolapse (Nichols). 1991;164:1155-8 (Clin. opinion)

Fatty acids
Decreased levels of polyunsaturated fatty acids in preeclampsia (Wang et al). 1991;164:812-8
Gestational age in relation to marine *n*-3 fatty acids in maternal erythrocytes: a study of women in the Faroe Islands and Denmark (Olsen et al). 1991;164:1203-9

Fatty liver
Should routine liver biopsy be done for the definite diag-

Fatty liver—cont'd
nosis of acute fatty liver of pregnancy? (Minakami et al) (Letter); (Barton and Sibai) (Reply). 1991;164:1690-1
Fertility
Fertility retention in the patient with genital prolapse (Nichols). 1991;164:1155-8 (Clin. opinion)
Fertilization
Prospective analysis of sperm-oocyte fusion and reactive oxygen species generation as criteria for the diagnosis of infertility (Aitken et al). 1991;164:542-51
Fertilization in vitro
Heterotopic pregnancies after in vitro fertilization and embryo transfer (Rizk et al). 1991;164:161-4
Multinuclear spermatozoa associated with polyploidy (Parikh et al). 1991;164:128-9
Ovarian response in superovulated cycles after suppression with oral contraceptive steroids (Burry et al). 1991;164:1592-6
Pregnancy rates after peritoneal ovum-sperm transfer (Coulam et al). 1991;164:1447-52
Recurrent failure of in vitro fertilization: role of the hemizona assay in the sequential diagnosis of specific sperm-oocyte defects (Oehninger et al). 1991;164:1210-5
Fetal anoxia
Mechanisms of asphyxial brain damage, and possible pharmacologic interventions, in the fetus (Espinoza and Parer). 1991;164:1582-91
Fetal asphyxia; *see* **Fetal anoxia**
Fetal biophysical profile; *see* **Fetal monitoring**
Fetal blood
The action of nitric oxide in the perfused human fetal-placental circulation (Myatt et al). 1991;164:687-92
Anesthesia and funic acid-base values (Camann) (Letter); (Shyken et al) (Reply). 1991;164:1360-1
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63
The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation (Bernardini et al). 1991; 164:1481-90
Fetal thyroid-stimulating hormone response to maternal administration of thyrotropin-releasing hormone (Thorpe-Beeston et al). 1991;164:1244-5
In utero diagnosis and management of fetal subdural hematoma (Rotmensch et al). 1991;164:1246-8
Serum levels of inhibin in maternal and umbilical blood during pregnancy (Tabei et al). 1991;164:896-900
Transvaginal color Doppler imaging in the assessment of uteroplacental blood flow in the normal first-trimester pregnancy (Jaffe and Warsof). 1991;164:781-5
Umbilical cord ulceration and intestinal atresia: A new association? (Bendon et al). 1991;164:582-6
Fetal blood, animal
Diastolic circulatory dynamics in the presence of elevated placental resistance and retrograde diastolic flow in the umbilical artery: a Doppler echographic study in lambs (Fouron et al). 1991;164:195-203
The effect of volume expansion on placental blood flow in awake hypovolemic rats in late pregnancy (Boekkooi et al). 1991;164:921-6
Evaluation of changes in umbilical blood flow in the fetal lamb by Doppler waveform analysis (Schmidt et al). 1991;164:1118-26
Fetal brain damage; *see* **Brain injuries**
Fetal breathing movements; *see* **Fetal organ maturity**
Fetal death
Early neonatal mortality and cesarean delivery in Mexico City (Bobadilla and Walker). 1991;164:22-8
Fetal death associated with measles virus infection of the placenta (Moroi et al). 1991;164:1107-8
Fetal subdural hematoma before labor (Gunn and Becroft) (Letter); (Myers) (Reply). 1991;164:934-5
Flow velocity waveforms of the fetal circulation preceding fetal death in a case of lupus anticoagulant (Mari and Wasserstrum). 1991;164:776-8
Genotyping of macerated stillborn fetuses (Derom et al). 1991;164:797-800
Hospital setting and fetal death during labor among women at low risk (Albers and Savitz). 1991;164:868-73
Intravenous immunoglobulin treatment of recurrent pregnancy loss and antiphospholipid antibodies (Orvieto et al). 1991;164:1687-8 (Letter)
Significance of oligohydramnios complicating pregnancy (Shenker et al). 1991;164:1597-600
Fetal development
Cell adhesion molecules and the regulation of development (Cunningham). 1991;164:939-48
Cross-sectional analysis of triplet birth weight (Jones et al). 1991;164:135-40
Frontothalamic measurement in the second trimester of pregnancy (Crade et al). 1991;164:704-5 (Letter)
The role of the placenta in nutrition of the human fetus (Schneider). 1991;164:967-73
Tables for estimation of individual risks of fetal neural tube and ventral wall defects, incorporating prior probability, maternal serum α-fetoprotein levels, and ultrasonographic examination results (Thornton et al). 1991;164:154-60
Transvaginal ultrasonographic definition of the central nervous system in the first and early second trimesters (Timor-Tritsch et al). 1991;164:497-503
The transverse cerebellar diameter in the second trimester is unaffected by Down syndrome (Hill et al). 1991;164:101-3
Fetal development, animal
Immunohistochemical localization of gonadotropin-releasing hormone during implantation in the New Zealand White rabbit (Bergh et al). 1991;164:1127-31
Fetal diseases, animal
Evaluation of changes in umbilical blood flow in the fetal lamb by Doppler waveform analysis (Schmidt et al). 1991;164:1118-26
Fetal distress
Fetal distress (Ramasubramanian et al). 1991;164:1151-2 (Letter)
Fetal electrocardiogram; *see* **Electrocardiography**
Fetal growth retardation
Comparison of associated high-risk factors and perinatal outcome between symmetric and asymmetric fetal intrauterine growth retardation (Lin et al). 1991;164:1535-42
The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation (Bernardini et al). 1991;164: 1481-90
Flow velocity waveforms of the fetal circulation preceding fetal death in a case of lupus anticoagulant (Mari and Wasserstrum). 1991;164:776-8
The relationship between autoantibodies and intrauterine growth retardation in hypertensive disorders of pregnancy (El-Roeiy et al). 1991;164:1253-61

Fetal heart
- Cardiac function in fetuses of type I diabetic mothers (Rizzo et al). 1991;164:837-43

Fetal heart rate; *see* **Heart rate, fetal**

Fetal hydrops; *see* **Hydrops fetalis**

Fetal macrosomia
- Glucose challenge testing in pregnancy (Neilson et al). 1991;164:1673-9
- Maternal postprandial glucose levels and infant birth weight: the Diabetes in Early Pregnancy Study (Jovanovic-Peterson et al). 1991;164:103-11
- Postterm infants: Too big or too small? (McLean et al). 1991;164:619-24

Fetal membranes
- Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
- Progress in pathogenesis and management of clinical intraamniotic infection (Gibbs and Duff). 1991;164:1317-26 (Curr. dev.)

Fetal membranes, animal
- Rapid intramembranous absorption into the fetal circulation of arginine vasopressin injected intraamniotically (Gilbert et al). 1991;164:1013-20

Fetal membranes, premature rupture
- Amniotic fluid glucose and intraamniotic infection (Kirshon et al). 1991;164:818-20
- Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
- *Chlamydia trachomatis* infection during pregnancy (McGregor and French). 1991;164:1782-9
- Epidemiologic characteristics of preterm delivery: etiologic heterogeneity (Savitz et al). 1991;164:467-71 (Clin. opinion)
- Fetal breathing movements after preterm premature rupture of membranes (Roberts et al). 1991;164:821-5
- Fetal urine output does not influence residual amniotic fluid volume after premature rupture of membranes (Watson et al). 1991;164:64-5
- Human amniotic fluid modulation of collagenase production in cultured fibroblasts (Vadillo-Ortega et al). 1991;164:664-8
- A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42
- The relationships among umbilical artery velocimetry, fetal biophysical profile, and placental inflammation in preterm premature rupture of the membranes (Fleming et al). 1991;164:38-41
- Significance of oligohydramnios complicating pregnancy (Shenker et al). 1991;164:1597-600

Fetal monitoring
- The contributions of the nurse and the machine in home uterine activity monitoring systems (Merkatz and Merkatz). 1991;164:1159-62 (Clin. opinion)
- Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9
- Fetal vibratory acoustic stimulation in twin gestations with simultaneous fetal heart rate monitoring (Sherer et al). 1991;164:1104-6
- Flow velocity waveforms of the fetal circulation preceding fetal death in a case of lupus anticoagulant (Mari and Wasserstrum). 1991;164:776-8
- The intrauterine probe electrode (Strong et al). 1991;164:1233-4
- Prevention of preterm birth in high-risk patients: the role of education and provider contact versus home uterine monitoring (Dyson et al). 1991;164:756-62
- The relationships among umbilical artery velocimetry, fetal biophysical profile, and placental inflammation in preterm premature rupture of the membranes (Fleming et al). 1991;164:38-41

Fetal movement
- Fast-scan magnetic resonance imaging in fetal visualization (Garden et al). 1991;164:1190-6
- Fetal panting: yet another response to the external vibratory acoustic stimulation test (Sherer et al). 1991;164:591-2

Fetal movement, animal
- Behavioral changes in fetal sheep caused by vibroacoustic stimulation: the effects of cochlear ablation (Parkes et al). 1991;164:1336-43

Fetal organ maturity
- Fetal breathing movements after preterm premature rupture of membranes (Roberts et al). 1991;164:821-5
- Frontothalamic measurement in the second trimester of pregnancy (Crade et al). 1991;164:704-5 (Letter)

Fetal organ maturity, animal
- Dose effects of antenatal corticosteroids for induction of lung maturation in preterm rabbits (Tabor et al). 1991;164:675-81

Fetal outcome; *see* **Pregnancy outcome**

Fetal-placental circulation; *see* **Fetal blood**

Fetal proteins
- Maternal serum α-fetoprotein screening: further consideration of low-volume testing (Strickland et al). 1991;164:711-4 (Clin. opinion)

Fetal tissue transplantation, animal
- Transplantation of fetal cells (Crombleholme et al). 1991;164:218-30 (Curr. dev.)

Fetofetal transfusion
- Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33

Fetomaternal transfusion
- Umbilical vein administration of oxytocin for the management of retained placenta: Is it effective? (Huber et al). 1991;164:1216-9

Fetus, abnormalities
- Fetal choroid plexus cysts in the second trimester of pregnancy: a cause for concern (Platt et al). 1991;164:1652-6
- Fetal ovarian cysts: prenatal ultrasonographic detection and postnatal evaluation and treatment (Meizner et al). 1991;164:874-8
- Mild fetal lateral cerebral ventriculomegaly: clinical course and outcome (Bromley et al). 1991;164:863-7
- Venous Doppler ultrasonography in the fetus with nonimmune hydrops (Gudmundsson et al). 1991;164:33-7
- Webster should not affect prenatal diagnosis (Barr et al) (Letter); (Chavkin and Rosenfield) (Reply). 1991;164:706-7

Fetus, anatomy
- Fast-scan magnetic resonance imaging in fetal visualization (Garden et al). 1991;164:1190-6

Fetus, ultrasonography
- The roles of ultrasonography and amniocentesis in evaluation of elevated maternal serum α-fetoprotein (Lindfors et al). 1991;164:1571-6

Fetus, urine
Fetal urine output does not influence residual amniotic fluid volume after premature rupture of membranes (Watson et al). 1991;164:64-5
Fibroadenosis; *see* **Adenofibroma**
Fibroblasts
Human amniotic fluid modulation of collagenase production in cultured fibroblasts (Vadillo-Ortega et al). 1991;164:664-8
Fibrocystic disease of breast
Fibrocystic disease of the breast in premenopausal women: histohormonal correlation and response to luteinizing hormone–releasing hormone analog treatment (Monsonego et al). 1991;164:1181-9
First trimester of pregnancy; *see* **Pregnancy trimester, first**
Fistula
Spontaneous ovarian-to-vaginal fistula: a case report (Claman et al). 1991;164:71-2
Flow velocity waveforms; *see* **Blood flow velocity**
Flowmeters
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63
Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33
Fluoresceins
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Fluoxetine
A selective serotonin reuptake inhibitor, fluoxetine hydrochloride, modulates the pulsatile release of prolactin in postmenopausal women (Urban and Veldhuis). 1991;164:147-52
Flurbiprofen
A comparison of flurbiprofen, tranexamic acid, and a levonorgestrel-releasing intrauterine contraceptive device in the treatment of idiopathic menorrhagia (Milsom et al). 1991;164:879-83
Follicular phase
The induction of premature luteolysis in normal women—follicular phase luteinizing hormone secretion and corpus luteum function in the subsequent cycle (Soules et al). 1991;164:989-96
Follow-up studies
Ten-year follow-up of patients with secondary amenorrhea and normal prolactin (Davajan et al). 1991;164:1666-72
Forskolin
Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Funic blood; *see* **Fetal blood**

G

Genes, myc
c-myc Protooncogene polypeptide expression in endometriosis (Schenken et al). 1991;164:1031-7
Genetic counseling
Genotyping of macerated stillborn fetuses (Derom et al). 1991;164:797-800
Low level of maternal serum α-fetoprotein: its associated anxiety and the effects of genetic counseling (Keenan et al). 1991;164:54-6
Genetic screening
Carrier screening for cystic fibrosis: implications for obstetric and gynecologic practice (Elias et al). 1991;164:1077-83 (Clin. opinion)
Maternal serum α-fetoprotein screening: further consideration of low-volume testing (Strickland et al). 1991;164:711-4 (Clin. opinion)
Genetics
A prospective genetic study of complete and partial hydatidiform moles (Lawler et al). 1991;164:1270-7
Restriction fragment length polymorphism analysis to study the genetic origin of complete hydatidiform mole (Ko et al). 1991;164:901-6
Genital diseases, female
Antisperm antibodies to sperm surface antigens in women with genital tract infection (Cunningham et al). 1991;164:791-6
Ultrasonography in the diagnosis of gynecologic disorders (Willson). 1991;164:1064-71
Genital herpes; *see* **Herpes genitalis**
Genital neoplasms, female
Assessment of current International Federation of Gynecology and Obstetrics staging of vulvar carcinoma relative to prognostic factors for survival (A Gynecologic Oncology Group Study) (Homesley et al). 1991;164:997-1004
The value of squamous cell carcinoma antigen in patients with locally advanced cervical cancer undergoing neoadjuvant chemotherapy (Scambia et al). 1991;164:631-6
Genital prolapse; *see* **Uterine prolapse**
Genotype
Genotyping of macerated stillborn fetuses (Derom et al). 1991;164:797-800
Gestational age
Birth weights of infants of black and white mothers without pregnancy complications (Hulsey et al). 1991;164:1299-302
The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation (Bernardini et al). 1991;164:1481-90
Gestational age in relation to marine *n*-3 fatty acids in maternal erythrocytes: a study of women in the Faroe Islands and Denmark (Olsen et al). 1991;164:1203-9
Gestational diabetes; *see* **Pregnancy in diabetes**
Gestational trophoblastic tumor; *see* **Trophoblastic tumor**
Giant cell arteritis; *see* **Temporal arteritis**
Gliomatosis peritonei; *see* **Ovarian neoplasms**
Glucose
Amniotic fluid glucose and intraamniotic infection (Kirshon et al). 1991;164:818-20
Maternal postprandial glucose levels and infant birth weight: the Diabetes in Early Pregnancy Study (Jovanovic-Peterson et al). 1991;164:103-11
Glucose tolerance test
Effect of subject height on the result for the fifty-gram oral glucose tolerance test (Phillipou). 1991;164:698 (Letter)
Glucose challenge testing in pregnancy (Neilson et al). 1991;164:1673-9
Reproducibility of the oral glucose tolerance test in pregnancy (Harlass et al). 1991;164:564-8
Glyceryl trinitrate
The hemodynamic effects of intubation during nitroglycerin infusion in severe preeclampsia (Longmire et al). 1991;164:551-6
Glycosylated hemoglobin; *see* **Hemoglobin A, glycosylated**
GnRH; *see* **Gonadorelin**

Goiter
The effects of iodoprophylaxis on thyroid size during pregnancy (Romano et al). 1991;164:482-5
Gonadorelin
Fibrocystic disease of the breast in premenopausal women: histohormonal correlation and response to luteinizing hormone–releasing hormone analog treatment (Monsonego et al). 1991;164:1181-9
Immunohistochemical localization of gonadotropin-releasing hormone during implantation in the New Zealand White rabbit (Bergh et al). 1991;164:1127-31
A randomized trial evaluating leuprolide acetate before hysterectomy as treatment for leiomyomas (Stovall et al). 1991;164:1420-5
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94
Gonadotropin-releasing hormone; *see* **Gonadorelin**
Gonadotropins, chorionic
hCG or β-hCG or hCG β-subunit or hCG + hCG β-subunit? (Kuss) (Letter); (Schiff et al) (Reply). 1991;164:1689
Gonadotropins, pituitary
Ovarian response in superovulated cycles after suppression with oral contraceptive steroids (Burry et al). 1991;164:1592-6
Gonorrhea
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
The role of azalide antibiotics in the treatment of chlamydia (Johnson). 1991;164:1794-6
Graft vs. host disease
Transplantation of fetal cells (Crombleholme et al). 1991;164:218-30 (Curr. dev.)
Growth retarded fetus; *see* **Fetal growth retardation**
Gynecologic diseases; *see* **Genital diseases, female**
Gynecologic neoplasms; *see* **Genital neoplasms, female**

H

Hallermann's syndrome
Successful pregnancy in a patient with Hallermann-Streiff syndrome (Hendrix and Sauer). 1991;164:1102-4
hCG; *see* **Gonadotropins, chorionic**
Health care delivery; *see* **Delivery of health care**
Heart auscultation
Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9
Heart failure, congestive
Venous Doppler ultrasonography in the fetus with nonimmune hydrops (Gudmundsson et al). 1991;164:33-7
Heart function tests
Cardiac function in fetuses of type I diabetic mothers (Rizzo et al). 1991;164:837-43
Heart rate, fetal
Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9
Fetal vibratory acoustic stimulation in twin gestations with simultaneous fetal heart rate monitoring (Sherer et al). 1991;164:1104-6
The intrauterine probe electrode (Strong et al). 1991;164:1233-4
The significance of amniotic fluid volume during intrapartum fetal acoustic stimulation (Sarno). 1991;164:1100-1
Umbilical artery blood flow velocity waveforms during variable decelerations of the fetal heart rate (Weiss et al). 1991;164:534-40
Heart rate, fetal, animal
Behavioral changes in fetal sheep caused by vibroacoustic stimulation: the effects of cochlear ablation (Parkes et al). 1991;164:1336-43
HELLP syndrome; *see* **Pregnancy complications, hematologic**
Hemangiosarcoma
Angiosarcoma of the uterus: a case report (Quinonez et al). 1991;164:90-2
Hematoma, subdural
Fetal subdural hematoma before labor (Gunn and Becroft) (Letter); (Myers) (Reply). 1991;164:934-5
In utero diagnosis and management of fetal subdural hematoma (Rotmensch et al). 1991;164:1246-8
Hematopoietic stem cells, transplantation
Transplantation of fetal cells (Crombleholme et al). 1991;164:218-30 (Curr. dev.)
Hemizona assay; *see* **Biological assay**
Hemodynamics
Position change and central hemodynamic profile during normal third-trimester pregnancy and post partum (Clark et al). 1991;164:883-7
Hemoglobin A, glycosylated
Maternal postprandial glucose levels and infant birth weight: the Diabetes in Early Pregnancy Study (Jovanovic-Peterson et al). 1991;164:103-11
Hemolysis
Mechanisms of hemolysis and anemia associated with acute antepartum pyelonephritis (Cox et al). 1991;164:587-90
The natural history of HELLP syndrome: patterns of disease progression and regression (Martin et al). 1991;164:1500-13
Preeclampsia as the great imposter (Goodlin). 1991;164:1577-81
Should routine liver biopsy be done for the definite diagnosis of acute fatty liver of pregnancy? (Minakami et al) (Letter); (Barton and Sibai) (Reply). 1991;164:1690-1
Hemorrhage
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8
Thumbtacks (Sutton). 1991;164:931-2 (Letter)
Hemostasis, surgical
Thumbtacks (Sutton). 1991;164:931-2 (Letter)
Hepatic vein thrombosis
Budd-Chiari syndrome, obstetric complications, and antiphospholipid antibodies (Cowchock) (Letter); (Ilan et al) (Reply). 1991;164:235
Hernia, umbilical
Tables for estimation of individual risks of fetal neural tube and ventral wall defects, incorporating prior probability, maternal serum α-fetoprotein levels, and ultrasono-

Hernia, umbilical—cont'd
graphic examination results (Thornton et al). 1991;164:154-60

Herpes genitalis
Incidence of genital herpes simplex virus at the time of delivery in women with known risk factors (Catalano et al). 1991;164:1303-6
Pharmacokinetics of acyclovir in the term human pregnancy and neonate (Frenkel et al). 1991;164:569-76

Herpes gestationis
Recurrent herpes gestationis with postpartum flare: a case report (Baxi et al). 1991;164:778-80

Herpesvirus hominis
Incidence of genital herpes simplex virus at the time of delivery in women with known risk factors (Catalano et al). 1991;164:1303-6

Heterotopic pregnancy; *see* **Pregnancy, ectopic**

Heterozygote detection
Carrier screening for cystic fibrosis: implications for obstetric and gynecologic practice (Elias et al). 1991;164:1077-83 (Clin. opinion)

Hispanic Americans
Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9

HIV
Human immunodeficiency virus–induced immunosuppression: a risk factor for human papillomavirus infection (Matorras et al). 1991;164:42-4
The increased frequency of cervical dysplasia-neoplasia in women infected with the human immunodeficiency virus is related to the degree of immunosuppression (Schäfer et al). 1991;164:593-9
Unraveling the mysteries of vulval ulceration in human immunodeficiency virus–seropositive women (Kell and Barton) (Letter); (Covino and McCormack) (Reply). 1991;164:935-6

Home nursing
The contributions of the nurse and the machine in home uterine activity monitoring systems (Merkatz and Merkatz). 1991;164:1159-62 (Clin. opinion)

Home uterine monitoring; *see* **Home nursing**

Hormonal replacement therapy; *see* **Estrogen replacement therapy**

Hormones
Reduction of cardiovascular disease–related mortality among postmenopausal women who use hormones: evidence from a national cohort (Wolf et al). 1991;164:489-94

Hospitals
Hospital setting and fetal death during labor among women at low risk (Albers and Savitz). 1991;164:868-73

Human immunodeficiency viruses; *see* **HIV**

Human papillomavirus deoxyribonucleic acid detection; *see* **DNA probes, HPV**

Human papillomaviruses; *see* **Papillomaviruses**

Human rights
The issue of animal rights and human rights (Maharry). 1991;164:1543-8 (Pres. address)

Hydatidiform mole
A prospective genetic study of complete and partial hydatidiform moles (Lawler et al). 1991;164:1270-7
Restriction fragment length polymorphism analysis to study the genetic origin of complete hydatidiform mole (Ko et al). 1991;164:901-6

Hydronephrosis
Urinary tract dilatation in pregnancy (Brown). 1991;164:642-3

Hydrops fetalis
Intrauterine transfusion treatment of nonimmune hydrops fetalis secondary to human parvovirus B19 infection (Sahakian et al). 1991;164:1090-1
Nonimmune hydrops in fetal Niemann-Pick disease (Vidgoff) (Letter); (Meizner) (Reply). 1991;164:231-2
Transplacental, amniotic, urinary, and fetal fluid dynamics during very-large-volume fetal intravenous infusions (Brace and Moore). 1991;164:907-16
Venous Doppler ultrasonography in the fetus with nonimmune hydrops (Gudmundsson et al). 1991;164:33-7

Hyperprolactinemia
Ten-year follow-up of patients with secondary amenorrhea and normal prolactin (Davajan et al). 1991;164:1666-72

Hypertension
Antepartum testing in the hypertensive patient: when to begin (Pircon et al). 1991;164:1563-70
Blood pressure self-monitoring during pregnancy: practical considerations (Zuspan and Rayburn). 1991;164:2-6 (Clin. opinion)
Complexes of activated protein C with α_1-antitrypsin in normal pregnancy and in severe preeclampsia (España et al) 1991;164:1310-6
Continuous electrocardiographic monitoring in hypertensive crises in pregnancy (Naidoo et al). 1991;164:530-3
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50
Endothelial-derived relaxing factor released by endothelial cells of human umbilical vessels and its impairment in pregnancy-induced hypertension (Pinto et al). 1991;164:507-13
Management of severe preeclampsia detected in early labor by prostaglandin A_1 or dihydralazine infusions (Toppozada et al). 1991;164:1229-32
The N-terminal and C-terminal portions of the atrial natriuretic factor prohormone increase during preeclampsia (Merkouris et al). 1991;164:1197-202
Preeclampsia as the great imposter (Goodlin). 1991;164:1577-81
The relationship between autoantibodies and intrauterine growth retardation in hypertensive disorders of pregnancy (El-Roeiy et al). 1991;164:1253-61

Hypertension, portal
Endoscopic sclerotherapy in extrahepatic portal hypertension in pregnancy (Pauzner et al). 1991;164:152-3

Hypnotics and sedatives
Outpatient sedation: an essential addition to gynecologic care for persons with mental retardation (Rosen et al). 1991;164:825-8

Hypotension, orthostatic
Position change and central hemodynamic profile during normal third-trimester pregnancy and post partum (Clark et al). 1991;164:883-7

Hypothalamus, animal
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conju-

gated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Cocaine in pregnancy: the effect of maternal administration of cocaine on the maternal and fetal pituitary-adrenal axes (Owiny et al). 1991;164:658-63

Hypothermia
Association between hypothermia and mortality rate of premature infants—revisited (Hazan et al). 1991;164:111-2

Hypothermia, induced, animal
Factors influencing the initiation of nonshivering thermogenesis (Gunn et al). 1991;164:210-7

Hysterectomy
Dissection of the cardinal ligament in radical hysterectomy for cervical cancer with emphasis on the lateral ligament (Yabuki et al). 1991;164:7-14 (Clin. opinion)
A randomized trial evaluating leuprolide acetate before hysterectomy as treatment for leiomyomas (Stovall et al). 1991;164:1420-5
Sacrospinous fixation—Should this be performed at the time of vaginal hysterectomy? (Cruikshank). 1991;164:1072-6 (Clin. opinion)

Hysterosalpingography
Hysterosalpingography with color Doppler ultrasonography (Peters and Coulam). 1991;164:1530-4

Hysteroscopy
Argon laser versus microscissors for hysteroscopic incision of uterine septa (Candiani et al). 1991;164:87-90
Embryoscopy: old technique new for the 1990s? (Ghirardini) (Letter); (Cullen et al) (Reply). 1991;164:1361-2
Hormonal inhibition of the endometrium for resectoscopic endometrial ablation (Brooks et al). 1991;164:1601-8

I

Ibuprofen
Koch's postulates: Revisited or revised? (Krumholz). 1991;164:704 (Letter)

Immunity, cellular
Regulation of the immune response to *Candida albicans* by monocytes and progesterone (Kalo-Klein and Witkin). 1991;164:1351-4

Immunocytochemistry; *see* **Immunohistochemistry**

Immunoglobulins
Intravenous immunoglobulin treatment of recurrent pregnancy loss and antiphospholipid antibodies (Orvieto et al). 1991;164:1687-8 (Letter)

Immunohistochemistry
Immunohistochemical localization of gonadotropin-releasing hormone during implantation in the New Zealand White rabbit (Bergh et al). 1991;164:1127-31
c-myc Protooncogene polypeptide expression in endometriosis (Schenken et al). 1991;164:1031-7

Immunology
Analysis of antigen expression at multiple tumor sites in epithelial ovarian cancer (Rubin et al). 1991;164:558-63

Immunosuppression
Human immunodeficiency virus–induced immunosuppression: a risk factor for human papillomavirus infection (Matorras et al). 1991;164:42-4
The increased frequency of cervical dysplasia-neoplasia in women infected with the human immunodeficiency virus is related to the degree of immunosuppression (Schäfer et al). 1991;164:593-9
Organ transplantation and pregnancy (Kirk). 1991;164:1629-34

In vitro fertilization; *see* **Fertilization in vitro**

Indomethacin
The effects of indomethacin and a β-sympathomimetic agent on the fetal ductus arteriosus during treatment of premature labor: a randomized double-blind study (Eronen et al). 1991;164:141-6
Randomized comparative trial of indomethacin and ritodrine for the long-term treatment of preterm labor (Besinger et al). 1991;164:981-8

Infant, low birth weight
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero (Laros et al). 1991;164:1657-65
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42
Small-for-gestational-age birth: maternal predictors and comparison with risk factors of spontaneous preterm delivery in the same cohort (Abrams and Newman). 1991;164:785-90
Weight gain by gestational age in both black and white women delivered of normal-birth-weight and low-birth-weight infants (Petitti et al). 1991;164:801-5

Infant, newborn
Birth weights of infants of black and white mothers without pregnancy complications (Hulsey et al). 1991;164:1299-302

Infant, newborn, diseases
Chlamydia trachomatis infection during pregnancy (McGregor and French). 1991;164:1782-9
Neonatal complications at term as related to the degree of umbilical artery acidemia (Winkler et al). 1991;164:637-41
Pharmacokinetics of acyclovir in the term human pregnancy and neonate (Frenkel et al). 1991;164:569-76

Infant, postmature
Postterm infants: Too big or too small? (McLean et al). 1991;164:619-24

Infant, premature
Anemia and spontaneous preterm birth (Klebanoff et al). 1991;164:59-63
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
Association between hypothermia and mortality rate of premature infants—revisited (Hazan et al). 1991;164:111-2
The biologic and social consequences of perinatal cocaine use in an inner-city population: results of an anonymous cross-sectional study (McCalla et al). 1991;164:625-30
The contributions of the nurse and the machine in home uterine activity monitoring systems (Merkatz and Merkatz). 1991;164:1159-62 (Clin. opinion)
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63
Epidemiologic characteristics of preterm delivery: etiologic heterogeneity (Savitz et al). 1991;164:467-71 (Clin. opinion)
The mammary stimulation test—A predictor of preterm delivery? (Eden et al). 1991;164:1409-19
Phospholipase C activity in microorganisms associated with reproductive tract infection (McGregor et al). 1991;164:682-6
Prevention of preterm birth in high-risk patients: the role

Infant, premature—cont'd
of education and provider contact versus home uterine monitoring (Dyson et al). 1991;164:756-62
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42
Small-for-gestational-age birth: maternal predictors and comparison with risk factors of spontaneous preterm delivery in the same cohort (Abrams and Newman). 1991;164:785-90
Umbilical arterial and venous acid-base and blood gas values and the effect of chorioamnionitis on those values in a cohort of preterm infants (Hankins et al). 1991;164:1261-4
Infant, small for gestational age
Small-for-gestational-age birth: maternal predictors and comparison with risk factors of spontaneous preterm delivery in the same cohort (Abrams and Newman). 1991;164:785-90
Infant mortality
Association between hypothermia and mortality rate of premature infants—revisited (Hazan et al). 1991;164:111-2
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
Early neonatal mortality and cesarean delivery in Mexico City (Bobadilla and Walker). 1991;164:22-8
Hospital setting and fetal death during labor among women at low risk (Albers and Savitz). 1991;164:868-73
Infection; *see also* **Pregnancy complications, infectious**
Antimicrobials in the 1990s: expanded options for effective patient care—introduction (Faro). 1991;164:1369
Antimicrobials in the 1990s: expanded options for effective patient care—summary (Faro). 1991;164:1399-400
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Diagnosis and laparoscopic grading of acute salpingitis (Soper). 1991;164:1370-6
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
Intrauterine transfusion treatment of nonimmune hydrops fetalis secondary to human parvovirus B19 infection (Sahakian et al). 1991;164:1090-1
New directions in the diagnosis and therapy of urinary tract infections (Powers). 1991;164:1387-9
Patient costs for prophylaxis and treatment of obstetric and gynecologic surgical infections (Stein). 1991;164:1377-80
Phospholipase C activity in microorganisms associated with reproductive tract infection (McGregor et al). 1991;164:682-6
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
Susceptibility of female pelvic pathogens to oral antibiotic agents in patients who develop postpartum endometritis (Martens et al). 1991;164:1383-6
Infertility
Antisperm antibodies to sperm surface antigens in women with genital tract infection (Cunningham et al). 1991;164:791-6
The importance of the postcoital test (Check) (Letter); (Grimes and Griffith) (Reply). 1991;164:932-3
Periovulatory calcium channel blockade enhances reproductive performance in an animal model for endometriosis-associated subfertility (Steinleitner et al). 1991;164:949-52
Pregnancy rates after peritoneal ovum-sperm transfer (Coulam et al). 1991;164:1447-52
Prospective analysis of sperm-oocyte fusion and reactive oxygen species generation as criteria for the diagnosis of infertility (Aitken et al). 1991;164:542-51
Infusions, intravenous
Transplacental, amniotic, urinary, and fetal fluid dynamics during very-large-volume fetal intravenous infusions (Brace and Moore). 1991;164:907-16
Inhibin
Serum levels of inhibin in maternal and umbilical blood during pregnancy (Tabei et al). 1991;164:896-900
Injections, intradermal
The effect of sterile water blocks on low back labor pain (Trolle et al). 1991;164:1277-81
Insurance liability
Alternative liability insurance: a physician-owned captive insurance company (Lee). 1991;164:1680-5
Interferons
Therapy of persistent human papillomavirus disease with two different interferon species (Gall et al). 1991;164:130-4
Interleukin-6
Serum interleukin-6 levels correlate with disease status in patients with epithelial ovarian cancer (Berek et al). 1991;164:1038-43
International Federation of Gynecology and Obstetrics
Assessment of current International Federation of Gynecology and Obstetrics staging of vulvar carcinoma relative to prognostic factors for survival (A Gynecologic Oncology Group Study) (Homesley et al). 1991;164:997-1004
Internship and residency
Residency training and abortion (Rosenfield). 1991;164:1686 (Letter)
Intestinal atresia
Umbilical cord ulceration and intestinal atresia: A new association? (Bendon et al). 1991;164:582-6
Intraamniotic infection; *see* **Amniotic fluid**
Intraumbilical injection; *see* **Umbilical cord**
Intrauterine devices
A comparison of flurbiprofen, tranexamic acid, and a levonorgestrel-releasing intrauterine contraceptive device in the treatment of idiopathic menorrhagia (Milsom et al). 1991;164:879-83
Intrauterine diagnosis; *see* **Prenatal diagnosis**
Intrauterine growth retardation; *see* **Fetal growth retardation**
Intrauterine probe electrode; *see* **Electrodes**
Intravenous infusions; *see* **Infusions, intravenous**
Intubation, intratracheal
The hemodynamic effects of intubation during nitroglycerin infusion in severe preeclampsia (Longmire et al). 1991;164:551-6
Iodine
The effects of iodoprophylaxis on thyroid size during pregnancy (Romano et al). 1991;164:482-5
Isoxsuprine
Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero (Laros et al). 1991;164:1657-65

Items
Items. 1991;164:240, 708, 938, 1154, 1368, 1714

K

Karyotyping
Mild fetal lateral cerebral ventriculomegaly: clinical course and outcome (Bromley et al). 1991;164:863-7
Ketamine
Outpatient sedation: an essential addition to gynecologic care for persons with mental retardation (Rosen et al). 1991;164:825-8
Kidney, abnormalities
Significance of oligohydramnios complicating pregnancy (Shenker et al). 1991;164:1597-600
Kidney failure, acute
Steroid-responsive nephrotic syndrome with renal insufficiency in the first trimester of pregnancy (Uribe et al). 1991;164:568-9

L

Labor
The effect of sterile water blocks on low back labor pain (Trolle et al). 1991;164:1277-81
Hospital setting and fetal death during labor among women at low risk (Albers and Savitz). 1991;164:868-73
Incidence of genital herpes simplex virus at the time of delivery in women with known risk factors (Catalano et al). 1991;164:1303-6
Management of severe preeclampsia detected in early labor by prostaglandin A_1 or dihydralazine infusions (Toppozada et al). 1991;164:1229-32
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Morphologic changes in the human amnion epithelium that accompany labor as seen with scanning and transmission electron microscopy (Sonek et al). 1991;164:1174-80
A new model for objective assessment of cervical ripening: the effect of prostaglandin E_2 and prelabor contractility (Takahashi et al). 1991;164:1115-8
Questions about prophylactic intrapartum amnioinfusion (Chauhan) (Letter); (Strong) (Reply). 1991;164: 1365-6
Umbilical vein administration of oxytocin for the management of retained placenta: Is it effective? (Huber et al). 1991;164:1216-9
Labor, premature
Amniotic fluid glucose and intraamniotic infection (Kirshon et al). 1991;164:818-20
Anemia and spontaneous preterm birth (Klebanoff et al). 1991;164:59-63
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7
The contributions of the nurse and the machine in home uterine activity monitoring systems (Merkatz and Merkatz). 1991;164:1159-62 (Clin. opinion)
The effects of indomethacin and a β-sympathomimetic agent on the fetal ductus arteriosus during treatment of premature labor: a randomized double-blind study (Eronen et al). 1991;164:141-6
Epidemiologic characteristics of preterm delivery: etiologic heterogeneity (Savitz et al). 1991;164:467-71 (Clin. opinion)
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Predictive value: symptoms of preterm labor (Strickland) (Letter); (Creasy and Katz) (Reply). 1991;164:700-1
Prevention of preterm birth in high-risk patients: the role of education and provider contact versus home uterine monitoring (Dyson et al). 1991;164:756-62
Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80
Randomized comparative trial of indomethacin and ritodrine for the long-term treatment of preterm labor (Besinger et al). 1991;164:981-8
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42
Laparoscopy; *see* **Peritoneoscopy**
Larynx, artificial
Intraabdominal sound levels during vibroacoustic stimulation (Graham et al). 1991;164:1140-4
Laser surgery
Argon laser versus microscissors for hysteroscopic incision of uterine septa (Candiani et al). 1991;164:87-90
The use of potassium-titanyl-phosphate laser for laparoscopic removal of ovarian endometrioma (Marrs). 1991;164:1622-8
Leiomyoma
A randomized trial evaluating leuprolide acetate before hysterectomy as treatment for leiomyomas (Stovall et al). 1991;164:1420-5
Letters
Letters. 1991;164:231-7, 698-707, 931-6, 1151-3, 1360-6, 1686-91
Leuprolide
Hormonal inhibition of the endometrium for resectoscopic endometrial ablation (Brooks et al). 1991;164:1601-8
A randomized trial evaluating leuprolide acetate before hysterectomy as treatment for leiomyomas (Stovall et al). 1991;164:1420-5
Levonorgestrel
A comparison of flurbiprofen, tranexamic acid, and a levonorgestrel-releasing intrauterine contraceptive device in the treatment of idiopathic menorrhagia (Milsom et al). 1991;164:879-83
Liability, legal
Alternative liability insurance: a physician-owned captive insurance company (Lee). 1991;164:1680-5
Lidocaine
Effects of acute hypermagnesemia on the threshold for lidocaine-induced seizures in the rat (Choi et al). 1991;164:693-7
Ligaments
Dissection of the cardinal ligament in radical hysterectomy for cervical cancer with emphasis on the lateral ligament (Yabuki et al). 1991;164:7-14 (Clin. opinion)
Liposomes
Toxicities in rats with free versus liposomal encapsulated cisplatin (Potkul et al). 1991;164:652-8
Listeria infections
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62

Listeria infections—cont'd
Successful antepartum treatment of listeriosis (Kalstone). 1991;164:57-8
Liver, surgery
Should routine liver biopsy be done for the definite diagnosis of acute fatty liver of pregnancy? (Minakami et al) (Letter); (Barton and Sibai) (Reply). 1991;164:1690-1
Longitudinal studies
Calcium-regulating hormones and osteocalcin levels during pregnancy: a longitudinal study (Seki et al). 1991;164:1248-52
Low back pain; *see* **Backache**
Low birth weight infant; *see* **Infant, low birth weight**
Lung maturation in fetus; *see* **Fetal organ maturity**
Lupus
Flow velocity waveforms of the fetal circulation preceding fetal death in a case of lupus anticoagulant (Mari and Wasserstrum). 1991;164:776-8
Luteinizing hormone-releasing hormone; *see* **Gonadorelin**
Lymph node excision
Laparoscopic pelvic lymphadenectomy in the staging of early carcinoma of the cervix (Querleu et al). 1991;164:579-81

M

M-mode echocardiography; *see* **Echocardiography**
Macrophage activation
Macrophage-conditioned media enhance endometrial stromal cell proliferation in vitro (Olive et al). 1991;164:953-8
Periovulatory calcium channel blockade enhances reproductive performance in an animal model for endometriosis-associated subfertility (Steinleitner et al). 1991;164:949-52
Macrophages
Macrophage-conditioned media enhance endometrial stromal cell proliferation in vitro (Olive et al). 1991;164:953-8
Macrosomia in fetus; *see* **Fetal macrosomia**
Magnesium sulfate
Effects of acute hypermagnesemia on the threshold for lidocaine-induced seizures in the rat (Choi et al). 1991;164:693-7
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50
Magnetic resonance imaging
Fast-scan magnetic resonance imaging in fetal visualization (Garden et al). 1991;164:1190-6
In utero diagnosis and management of fetal subdural hematoma (Rotmensch et al). 1991;164:1246-8
Magnetic resonance spectroscopy; *see* **Nuclear magnetic resonance**
Magnification views; *see* **Radiographic magnification**
Mammary glands; *see* **Breast**
Mammary stimulation test
The mammary stimulation test—A predictor of preterm delivery? (Eden et al). 1991;164:1409-19
Mammography
Improved mammographic accuracy (Pillsbury et al). 1991;164:1643-6
Marine ***n*-3 fatty acids**; *see* **Fatty acids**
Maternal-fetal exchange
The role of the placenta in nutrition of the human fetus (Schneider). 1991;164:967-73
Maternal herpes simplex virus; *see* **Herpesvirus hominis**
Maternal mortality
Pregnancy-related mortality in New York City, 1980 to 1984: causes of death and associated risk factors (Syverson et al). 1991;164:603-8
Maternal weight; *see* **Body weight**
McCall's suture; *see* **Sutures**
Measles virus
Fetal death associated with measles virus infection of the placenta (Moroi et al). 1991;164:1107-8
Meconium
Inhibition of pulmonary surfactant function by meconium (Moses et al). 1991;164:477-81
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Medical care delivery system; *see* **Patient care team**
Medical history taking
The natural history of HELLP syndrome: patterns of disease progression and regression (Martin et al). 1991;164:1500-13
Medical records
Prenatal records: a national survey of content (Peoples-Sheps et al). 1991;164:514-21
Medicare
Clinical implications of screening for cervical cancer under Medicare (Mandelblatt et al). 1991;164:644-51 (Curr. dev.)
Menopause
The effects of hormone replacement therapy in normal postmenopausal women: measurements of Doppler-derived parameters of aortic flow (Pines et al). 1991;164:806-12
Reduction of cardiovascular disease–related mortality among postmenopausal women who use hormones: evidence from a national cohort (Wolf et al). 1991;164:489-94
A selective serotonin reuptake inhibitor, fluoxetine hydrochloride, modulates the pulsatile release of prolactin in postmenopausal women (Urban and Veldhuis). 1991;164:147-52
Vasoactive intestinal polypeptide loses its ability to increase vaginal blood flow after menopause (Palle et al). 1991;164:556-8
Menorrhagia
A comparison of flurbiprofen, tranexamic acid, and a levonorgestrel-releasing intrauterine contraceptive device in the treatment of idiopathic menorrhagia (Milsom et al). 1991;164:879-83
Menstrual cycle
The induction of premature luteolysis in normal women—follicular phase luteinizing hormone secretion and corpus luteum function in the subsequent cycle (Soules et al). 1991;164:989-96
Ovarian response in superovulated cycles after suppression with oral contraceptive steroids (Burry et al). 1991;164:1592-6
Menstruation
Endometrial thickness as measured by endovaginal ultrasonography for identifying endometrial abnormality (Granberg et al). 1991;164:47-52
Menstrual mythology and sources of information about menstruation (Cumming et al). 1991;164:472-6 (Clin. opinion)

Mental retardation
Outpatient sedation: an essential addition to gynecologic care for persons with mental retardation (Rosen et al). 1991;164:825-8
Mesonephroma
Endodermal sinus tumor of the ovary during pregnancy: a case report (van der Zee et al). 1991;164:504-6
Methotrexate
Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Methotrexate treatment of ectopic gestation and reproductive outcome (Egarter) (Letter); (Stovall et al) (Reply). 1991;164:698-700
Methotrexate treatment of tubal pregnancy (Bateman) (Letter); (Stovall et al) (Reply). 1991;164:231
Nonsurgical management of tubal pregnancy (Pansky et al). 1991;164:888-95 (Curr. dev.)
Microscopy, electron
Morphologic changes in the human amnion epithelium that accompany labor as seen with scanning and transmission electron microscopy (Sonek et al). 1991;164:1174-80
Microscopy, electron, scanning
Morphologic changes in the human amnion epithelium that accompany labor as seen with scanning and transmission electron microscopy (Sonek et al). 1991;164:1174-80
Midazolam
Outpatient sedation: an essential addition to gynecologic care for persons with mental retardation (Rosen et al). 1991;164:825-8
Mifepristone
Nonsurgical management of tubal pregnancy (Pansky et al). 1991;164:888-95 (Curr. dev.)
Misdiagnosis; *see* **Diagnostic errors**
Molecular structure
Cell adhesion molecules and the regulation of development (Cunningham). 1991;164:939-48
Monoamine oxidase
Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
Monocytes
Regulation of the immune response to *Candida albicans* by monocytes and progesterone (Kalo-Klein and Witkin). 1991;164:1351-4
Morphogenesis
Cell adhesion molecules and the regulation of development (Cunningham). 1991;164:939-48
Mortality, infant; *see* **Infant mortality**
Motrin; *see* **Ibuprofen**
Multiple birth; *see* **Pregnancy, multiple**
Muscle, smooth
Characterization of sodium channels in cultured human uterine smooth muscle cells (Young and Herndon-Smith). 1991;164:175-81
Muscle, smooth, vascular
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50
Muscular dystrophy
Prenatal diagnosis of myotonic muscular dystrophy with linked deoxyribonucleic acid probes (Milunsky et al). 1991;164:751-5
Myometrium
Passive membrane properties and inward calcium current of human uterine smooth muscle cells (Young et al). 1991;164:1132-9
Myotonia congenita
Prenatal diagnosis of myotonic muscular dystrophy with linked deoxyribonucleic acid probes (Milunsky et al). 1991;164:751-5

N

Natriuretic peptides, atrial
The N-terminal and C-terminal portions of the atrial natriuretic factor prohormone increase during preeclampsia (Merkouris et al). 1991;164:1197-202
Neisseria gonorrhoeae
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
The role of azalide antibiotics in the treatment of chlamydia (Johnson). 1991;164:1794-6
Neonatal mortality; *see* **Infant mortality**
Neonatal outcome; *see* **Pregnancy outcome**
Neonate; *see* **Infant, newborn**
Neoplasm invasiveness
Trends in the operative management of invasive squamous carcinoma of the vulva at Indiana University, 1974 to 1988 (Sutton et al). 1991;164:1472-81
Neoplasm staging
Assessment of current International Federation of Gynecology and Obstetrics staging of vulvar carcinoma relative to prognostic factors for survival (A Gynecologic Oncology Group Study) (Homesley et al). 1991;164:997-1004
Laparoscopic pelvic lymphadenectomy in the staging of early carcinoma of the cervix (Querleu et al). 1991;164:579-81
Neoplasms, glandular epithelial
Serum interleukin-6 levels correlate with disease status in patients with epithelial ovarian cancer (Berek et al). 1991;164:1038-43
Nephrostomy, percutaneous
Suture entrapment and secondary ureteral obstruction (Stanhope et al). 1991;164:1513-9
Nephrotic syndrome
Steroid-responsive nephrotic syndrome with renal insufficiency in the first trimester of pregnancy (Uribe et al). 1991;164:568-9
Neural tube defects
Maternal serum α-fetoprotein screening: further consideration of low-volume testing (Strickland et al). 1991;164:711-4 (Clin. opinion)
Tables for estimation of individual risks of fetal neural tube and ventral wall defects, incorporating prior probability, maternal serum α-fetoprotein levels, and ultrasonographic examination results (Thornton et al). 1991;164:154-60
Neurologic examination
Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9

Neuronal plasticity, animal
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Neuropeptide Y
Endothelin and neuropeptide Y are vasoconstrictors in human uterine blood vessels (Fried and Samuelson). 1991;164:1330-6
Neurosurgery
Lymphocytic adenohypophysitis: a pituitary mass lesion occurring in pregnancy (Feigenbaum et al). 1991;164:1549-55
Newborn; *see* **Infant, newborn**
Niemann-Pick disease
Nonimmune hydrops in fetal Niemann-Pick disease (Vidgoff) (Letter); (Meizner) (Reply). 1991;164:231-2
Nipples
The mammary stimulation test—A predictor of preterm delivery? (Eden et al). 1991;164:1409-19
Nitric oxide
The action of nitric oxide in the perfused human fetal-placental circulation (Myatt et al). 1991;164:687-92
Nitroglycerin; *see* **Glyceryl trinitrate**
Nonimmune hydrops; *see* **Hydrops fetalis**
Noradrenaline; *see* **Norepinephrine**
Norepinephrine
Endothelin and neuropeptide Y are vasoconstrictors in human uterine blood vessels (Fried and Samuelson). 1991;164:1330-6
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50
Norethindrone
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8
The effect of tetracycline on levels of oral contraceptives (Murphy et al). 1991;164:28-33
Oral contraceptives and antithrombin III: variations by dosage and ABO blood group (Burkman et al). 1991;164:1453-60
Norethisterone; *see* **Norethindrone**
Nuclear magnetic resonance
Phosphorus 31 magnetic resonance spectroscopy of human placenta and quantitation with perchloric acid extracts (Kay et al). 1991;164:80-7
Nutrition
The role of the placenta in nutrition of the human fetus (Schneider). 1991;164:967-73

O

Occupational health
Occupational vibration during pregnancy (Abrams and Wasserman). 1991;164:1152 (Letter)
Ofloxacin
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Effectiveness of ofloxacin in the treatment of *Chlamydia trachomatis* and *Neisseria gonorrhoeae* cervical infection (Faro et al). 1991;164:1380-3
A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6
Oligohydramnios
Koch's postulates: Revisited or revised? (Krumholz). 1991;164:704 (Letter)
Significance of oligohydramnios complicating pregnancy (Shenker et al). 1991;164:1597-600
Oncogenes
Overexpression of HER-2/*neu* in endometrial cancer is associated with advanced stage disease (Berchuck et al). 1991;164:15-21
c-*myc* Protooncogene polypeptide expression in endometriosis (Schenken et al). 1991;164:1031-7
Oocytes
Pregnancy rates after peritoneal ovum-sperm transfer (Coulam et al). 1991;164:1447-52
Prospective analysis of sperm-oocyte fusion and reactive oxygen species generation as criteria for the diagnosis of infertility (Aitken et al). 1991;164:542-51
Recurrent failure of in vitro fertilization: role of the hemizona assay in the sequential diagnosis of specific sperm-oocyte defects (Oehninger et al). 1991;164:1210-5
Oophorectomy; *see* **Ovariectomy**
Open spina bifida; *see* **Spina bifida cystica**
Oral contraceptives; *see* **Contraceptives, oral**
Organ transplantation
Organ transplantation and pregnancy (Kirk). 1991;164:1629-34
Osteocalcin
Calcium-regulating hormones and osteocalcin levels during pregnancy: a longitudinal study (Seki et al). 1991;164:1248-52
Outpatients
Outpatient sedation: an essential addition to gynecologic care for persons with mental retardation (Rosen et al). 1991;164:825-8
Ovarian cancer; *see* **Ovarian neoplasms**
Ovarian cycle; *see* **Menstrual cycle**
Ovarian cysts
Fetal ovarian cysts: prenatal ultrasonographic detection and postnatal evaluation and treatment (Meizner et al). 1991;164:874-8
Ovarian neoplasms
Analysis of antigen expression at multiple tumor sites in epithelial ovarian cancer (Rubin et al). 1991;164:558-63
The diagnosis of ovarian cancer by pathologists: How often do diagnoses by contributing pathologists agree with a panel of gynecologic pathologists? (Tyler et al). 1991;164:65-70
Endodermal sinus tumor of the ovary during pregnancy: a case report (van der Zee et al). 1991;164:504-6
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. I. Correlation of receptor expression with prognostic factors in patients with ovarian cancer (Berchuck et al). 1991;164:669-74
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. II. Relationship between receptor expression and response to epidermal growth factor (Rodriguez et al). 1991;164:745-50
Gliomatosis peritonei with malignant transformation: a case report and review of the literature (Shefren et al). 1991;164:1617-21
Ovarian neoplasms and the risk of adnexal torsion (Sommerville et al). 1991;164:577-8
Serum interleukin-6 levels correlate with disease status in patients with epithelial ovarian cancer (Berek et al). 1991;164:1038-43

Toxicities in rats with free versus liposomal encapsulated cisplatin (Potkul et al). 1991;164:652-8
Ultrasonography in the diagnosis of gynecologic disorders (Willson). 1991;164:1064-71

Ovariectomy
A risk-benefit analysis of elective bilateral oophorectomy: effect of changes in compliance with estrogen therapy on outcome (Speroff et al). 1991;164:165-74 (Curr. dev.)

Ovary
The diagnosis of ovarian cancer by pathologists: How often do diagnoses by contributing pathologists agree with a panel of gynecologic pathologists? (Tyler et al). 1991;164:65-70
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. I. Correlation of receptor expression with prognostic factors in patients with ovarian cancer (Berchuck et al). 1991;164:669-74
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. II. Relationship between receptor expression and response to epidermal growth factor (Rodriguez et al). 1991;164:745-50
Spontaneous ovarian-to-vaginal fistula: a case report (Claman et al). 1991;164:71-2

Ovulation, animal
Periovulatory calcium channel blockade enhances reproductive performance in an animal model for endometriosis-associated subfertility (Steinleitner et al). 1991;164:949-52

Ovum-sperm transfer, peritoneal; *see* **Fertilization in vitro**

Oxytocin
Intraumbilical injection of oxytocin (Chestnut) (Letter); (Golan) (Reply). 1991;164:702-3
Umbilical vein administration of oxytocin for the management of retained placenta: Is it effective? (Huber et al). 1991;164:1216-9

P

Pacific Coast Obstetrical and Gynecological Society
Transactions of the fifty-seventh annual meeting of the Pacific Coast Obstetrical and Gynecological Society. 1991;164:1543-685

Pain
Endosalpingosis as a cause of chronic pelvic pain (Davies and Maclin). 1991;164:495-6
Relationship of laparoscopic findings to self-report of pelvic pain (Stout et al). 1991;164:73-9

Papanicolaou smear; *see* **Vaginal smears**

Papillomaviruses
Human immunodeficiency virus–induced immunosuppression: a risk factor for human papillomavirus infection (Matorras et al). 1991;164:42-4
The increased frequency of cervical dysplasia-neoplasia in women infected with the human immunodeficiency virus is related to the degree of immunosuppression (Schäfer et al). 1991;164:593-9
Should cervical cytologic testing be augmented by cervicography or human papillomavirus deoxyribonucleic acid detection? (Reid et al). 1991;164:1461-71
Therapy of persistent human papillomavirus disease with two different interferon species (Gall et al). 1991;164:130-4

Parturition; *see* **Labor**

Parvovirus infections
Intrauterine transfusion treatment of nonimmune hydrops fetalis secondary to human parvovirus B19 infection (Sahakian et al). 1991;164:1090-1
Parvovirus transmission concerns (Donnenfeld and Schick-Boschetto) (Letter); (Rodis) (Reply). 1991;164:1363-4

Patient care team
Winter hath hope of spring (Malinak). 1991;164:1401-8 (Pres. address)

Patient compliance
Vaginal birth after cesarean section: the impact of patient resistance to a trial of labor (Joseph et al). 1991;164:1441-7

Patient costs; *see* **Cost benefit analysis**

Patient education
Prevention of preterm birth in high-risk patients: the role of education and provider contact versus home uterine monitoring (Dyson et al). 1991;164:756-62

Pelvic inflammatory disease; *see* **Adnexitis**

Pelvis
The accuracy of clinical findings and laparoscopy in pelvic inflammatory disease (Sellors et al). 1991;164:113-20
Endosalpingosis as a cause of chronic pelvic pain (Davies and Maclin). 1991;164:495-6
Relationship of laparoscopic findings to self-report of pelvic pain (Stout et al). 1991;164:73-9

Penicillins
Antibiotic treatment of tuboovarian abscess: comparison of broad-spectrum β-lactam agents versus clindamycin-containing regimens (Reed et al). 1991;164:1556-62

Pentamidine
Pharmacokinetics of pentamidine in Sprague-Dawley rats in late pregnancy (Little et al). 1991;164:927-30

Peptides
c-*myc* Protooncogene polypeptide expression in endometriosis (Schenken et al). 1991;164:1031-7

Perchloric acids
Phosphorus 31 magnetic resonance spectroscopy of human placenta and quantitation with perchloric acid extracts (Kay et al). 1991;164:80-7

Percutaneous nephrostomy; *see* **Nephrostomy, percutaneous**

Percutaneous umbilical blood sampling; *see* **Fetal blood**

Perinatal mortality; *see* **Infant mortality**

Perinatal outcome; *see* **Pregnancy outcome**

Perineorrhaphy; *see* **Perineum, surgery**

Perineum, surgery
Posterior colporrhaphy and perineorrhaphy: separate and distinct operations (Nichols). 1991;164:714-21 (Clin. opinion)

Peritoneal ovum-sperm transfer; *see* **Fertilization in vitro**

Peritoneoscopy
The accuracy of clinical findings and laparoscopy in pelvic inflammatory disease (Sellors et al). 1991;164:113-20
Diagnosis and laparoscopic grading of acute salpingitis (Soper). 1991;164:1370-6
Laparoscopic pelvic lymphadenectomy in the staging of early carcinoma of the cervix (Querleu et al). 1991;164:579-81
Relationship of laparoscopic findings to self-report of pelvic pain (Stout et al). 1991;164:73-9
The use of potassium-titanyl-phosphate laser for laparoscopic removal of ovarian endometrioma (Marrs). 1991;164:1622-8

Peritoneum
Endometriosis associated with massive ascites and absence

Peritoneum—cont'd
of pelvic peritoneum (Williams and Wagaman). 1991;164:45-6
Gliomatosis peritonei with malignant transformation: a case report and review of the literature (Shefren et al). 1991;164:1617-21
Peroxidases
Astrocytes within the hypothalamic arcuate nucleus contain estrogen-sensitive peroxidase, bind fluorescein-conjugated estradiol, and may mediate synaptic plasticity in the rat (Keefe et al). 1991;164:959-66
Phenethanolamine N-methyltransferase
Characterization of enzymes of catecholamine synthesis and metabolism in human fetal membranes at birth (Casimiri et al). 1991;164:599-603
Phenotype
Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Phenylethanolamine-N-methytransferase; *see* **Phenethanolamine N-methyltransferase**
Phospholipase C
Phospholipase C activity in microorganisms associated with reproductive tract infection (McGregor et al). 1991;164:682-6
Phosphorus isotopes
Phosphorus 31 magnetic resonance spectroscopy of human placenta and quantitation with perchloric acid extracts (Kay et al). 1991;164:80-7
Pituitary diseases
Lymphocytic adenohypophysitis: a pituitary mass lesion occurring in pregnancy (Feigenbaum et al). 1991;164:1549-55
Pituitary gland, anterior
Lymphocytic adenohypophysitis: a pituitary mass lesion occurring in pregnancy (Feigenbaum et al). 1991;164:1549-55
Pituitary gonadotropins; *see* **Gonadotropins, pituitary**
Pituitary hormones
Cocaine in pregnancy: the effect of maternal administration of cocaine on the maternal and fetal pituitary-adrenal axes (Owiny et al). 1991;164:658-63
Placenta
The action of nitric oxide in the perfused human fetal-placental circulation (Myatt et al). 1991;164:687-92
The fetal concentrating index as a gestational age–independent measure of placental dysfunction in intrauterine growth retardation (Bernardini et al). 1991;164:1481-90
Investigation of placental circulations by color Doppler ultrasonography (Jauniaux et al). 1991;164:486-8
Phosphorus 31 magnetic resonance spectroscopy of human placenta and quantitation with perchloric acid extracts (Kay et al). 1991;164:80-7
The relationships among umbilical artery velocimetry, fetal biophysical profile, and placental inflammation in preterm premature rupture of the membranes (Fleming et al). 1991;164:38-41
The role of the placenta in nutrition of the human fetus (Schneider). 1991;164:967-73
Serum levels of inhibin in maternal and umbilical blood during pregnancy (Tabei et al). 1991;164:896-900
Significance of oligohydramnios complicating pregnancy (Shenker et al). 1991;164:1597-600
Transvaginal color Doppler imaging in the assessment of uteroplacental blood flow in the normal first-trimester pregnancy (Jaffe and Warsof). 1991;164:781-5
Umbilical vein administration of oxytocin for the management of retained placenta: Is it effective? (Huber et al). 1991;164:1216-9
Placenta, animal
Transplacental, amniotic, urinary, and fetal fluid dynamics during very-large-volume fetal intravenous infusions (Brace and Moore). 1991;164:907-16
Placental blood flow; *see* **Fetal blood**
Placental function tests, animal
Diastolic circulatory dynamics in the presence of elevated placental resistance and retrograde diastolic flow in the umbilical artery: a Doppler echographic study in lambs (Fouron et al). 1991;164:195-203
Plasminogen activator, tissue-type
Synergistic effect of intraperitoneally administered calcium channel blockade and recombinant tissue plasminogen activator to prevent adhesion formation in an animal model (Dunn et al). 1991;164:1327-30
Platelet count
The natural history of HELLP syndrome: patterns of disease progression and regression (Martin et al). 1991;164:1500-13
Preeclampsia as the great imposter (Goodlin). 1991;164:1577-81
Quantitative and qualitative platelet abnormalities during pregnancy (How et al). 1991;164:92-8
Polymerase chain reaction
Intraamniotic detection of *Chlamydia trachomatis* deoxyribonucleic acid sequences by polymerase chain reaction (Pao et al). 1991;164:1295-9
Polymorphism; *see* **Genetics**
Polypeptides; *see* **Peptides**
Polyploidy
Multinuclear spermatozoa associated with polyploidy (Parikh et al). 1991;164:128-9
Polyunsaturated fatty acids; *see* **Fatty acids**
Portal hypertension; *see* **Hypertension, portal**
Postcoital test; *see* **Sperm count**
Postmenopause; *see* **Menopause**
Postpartum period; *see* **Puerperium**
Postpartum period disorders; *see* **Puerperal disorders**
Postpartum shock; *see* **Shock**
Potassium chloride
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50
Potassium-titanyl-phosphate laser; *see* **Laser surgery**
Pre-eclampsia
Blood pressure self-monitoring during pregnancy: practical considerations (Zuspan and Rayburn). 1991;164:2-6 (Clin. opinion)
Complexes of activated protein C with α_1-antitrypsin in normal pregnancy and in severe preeclampsia (España et al). 1991;164:1310-6
Decreased levels of polyunsaturated fatty acids in preeclampsia (Wang et al). 1991;164:812-8
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
The effect of volume expansion on placental blood flow in awake hypovolemic rats in late pregnancy (Boekkooi et al). 1991;164:921-6

The hemodynamic effects of intubation during nitroglycerin infusion in severe preeclampsia (Longmire et al). 1991;164:551-6

Management of severe preeclampsia detected in early labor by prostaglandin A_1 or dihydralazine infusions (Toppozada et al). 1991;164:1229-32

The N-terminal and C-terminal portions of the atrial natriuretic factor prohormone increase during preeclampsia (Merkouris et al). 1991;164:1197-202

The natural history of HELLP syndrome: patterns of disease progression and regression (Martin et al). 1991;164:1500-13

Preeclampsia as the great imposter (Goodlin). 1991;164:1577-81

The relationship between autoantibodies and intrauterine growth retardation in hypertensive disorders of pregnancy (El-Roeiy et al). 1991;164:1253-61

Predictive value of tests

The diagnosis of ovarian cancer by pathologists: How often do diagnoses by contributing pathologists agree with a panel of gynecologic pathologists? (Tyler et al). 1991;164:65-70

Improved mammographic accuracy (Pillsbury et al). 1991;164:1643-6

The mammary stimulation test—A predictor of preterm delivery? (Eden et al). 1991;164:1409-19

Predictive value: symptoms of preterm labor (Strickland) (Letter); (Creasy and Katz) (Reply). 1991;164:700-1

Pregnancy

Calcium-regulating hormones and osteocalcin levels during pregnancy: a longitudinal study (Seki et al). 1991;164:1248-52

The clinical utility of maternal body mass index in pregnancy (Wolfe et al). 1991;164:1306-10

Complexes of activated protein C with α_1-antitrypsin in normal pregnancy and in severe preeclampsia (España et al). 1991;164:1310-6

Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9

Effect of low-dose aspirin on vascular refractoriness in angiotensin-sensitive primigravid women (Wallenburg et al). 1991;164:1169-73

Human placenta expresses endothelin gene and corresponding protein is excreted in urine in increasing amounts during normal pregnancy (Benigni et al). 1991;164:844-8

Organ transplantation and pregnancy (Kirk). 1991;164:1629-34

Serum levels of inhibin in maternal and umbilical blood during pregnancy (Tabei et al). 1991;164:896-900

Pregnancy, animal

Effect of intravenous cocaine on uterine blood flow in the gravid baboon (Morgan et al). 1991;164:1021-30

The effect of volume expansion on placental blood flow in awake hypovolemic rats in late pregnancy (Boekkooi et al). 1991;164:921-6

Pharmacokinetics of pentamidine in Sprague-Dawley rats in late pregnancy (Little et al). 1991;164:927-30

Pregnancy, ectopic

Chlamydia trachomatis infection during pregnancy (McGregor and French). 1991;164:1782-9

Genital chlamydial infections: epidemiology and reproductive sequelae (Cates and Wasserheit). 1991;164:1771-81

Heterotopic pregnancies after in vitro fertilization and embryo transfer (Rizk et al). 1991;164:161-4

Methotrexate treatment of ectopic gestation and reproductive outcome (Egarter) (Letter); (Stovall et al) (Reply). 1991;164:698-700

Methotrexate treatment of tubal pregnancy (Bateman) (Letter); (Stovall et al) (Reply). 1991;164:231

Nonsurgical management of tubal pregnancy (Pansky et al). 1991;164:888-95 (Curr. dev.)

Pregnancy-related mortality in New York City, 1980 to 1984: causes of death and associated risk factors (Syverson et al). 1991;164:603-8

Pregnancy, multiple

Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33

Pregnancy, tubal

Methotrexate treatment of tubal pregnancy (Bateman) (Letter); (Stovall et al) (Reply). 1991;164:231

Nonsurgical management of tubal pregnancy (Pansky et al). 1991;164:888-95 (Curr. dev.)

Pregnancy, unwanted

Attitudes on the ethics of abortion, sex selection, and selective pregnancy termination among health care professionals, ethicists, and clergy likely to encounter such situations (Evans et al). 1991;164:1092-9

Pregnancy complications

Amniotic endothelin increase during pregnancy (Raboni et al). 1991;164:237 (Letter)

Antiepileptic medication in pregnancy: late effects on the children's central nervous system development (van der Pol et al). 1991;164:121-8

Budd-Chiari syndrome, obstetric complications, and antiphospholipid antibodies (Cowchock) (Letter); (Ilan et al) (Reply). 1991;164:235

CA 125 levels in abruptio placentae (Witt et al). 1991;164:1225-8

The clinical implications of subchorionic placental lucencies (Katz et al). 1991;164:99-100

Early neonatal mortality and cesarean delivery in Mexico City (Bobadilla and Walker). 1991;164:22-8

The effects of iodoprophylaxis on thyroid size during pregnancy (Romano et al). 1991;164:482-5

Fetal urine output does not influence residual amniotic fluid volume after premature rupture of membranes (Watson et al). 1991;164:64-5

Heterotopic pregnancies after in vitro fertilization and embryo transfer (Rizk et al). 1991;164:161-4

Maternal postprandial glucose levels and infant birth weight: the Diabetes in Early Pregnancy Study (Jovanovic-Peterson et al). 1991;164:103-11

Nonsurgical management of tubal pregnancy (Pansky et al). 1991;164:888-95 (Curr. dev.)

Occupational vibration during pregnancy (Abrams and Wasserman). 1991;164:1152 (Letter)

Predictive value: symptoms of preterm labor (Strickland) (Letter); (Creasy and Katz) (Reply). 1991;164:700-1

The relationships among umbilical artery velocimetry, fetal biophysical profile, and placental inflammation in preterm premature rupture of the membranes (Fleming et al). 1991;164:38-41

Significance of oligohydramnios complicating pregnancy (Shenker et al). 1991;164:1597-600

Steroid-responsive nephrotic syndrome with renal insuffi-

Pregnancy complications—cont'd
ciency in the first trimester of pregnancy (Uribe et al). 1991;164:568-9
Successful pregnancy in a patient with Hallermann-Streiff syndrome (Hendrix and Sauer). 1991;164:1102-4
Urinary tract dilatation in pregnancy (Brown). 1991;164:642-3
Venous Doppler ultrasonography in the fetus with nonimmune hydrops (Gudmundsson et al). 1991;164:33-7

Pregnancy complications, cardiovascular
Antepartum testing in the hypertensive patient: when to begin (Pircon et al). 1991;164:1563-70
Blood pressure self-monitoring during pregnancy: practical considerations (Zuspan and Rayburn). 1991;164:2-6 (Clin. opinion)
Complexes of activated protein C with α_1-antitrypsin in normal pregnancy and in severe preeclampsia (España et al). 1991;164:1310-6
Continuous electrocardiographic monitoring in hypertensive crises in pregnancy (Naidoo et al). 1991;164:530-3
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50
Endoscopic sclerotherapy in extrahepatic portal hypertension in pregnancy (Pauzner et al). 1991;164:152-3
Endothelial-derived relaxing factor released by endothelial cells of human umbilical vessels and its impairment in pregnancy-induced hypertension (Pinto et al). 1991;164:507-13
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50
Management of severe preeclampsia detected in early labor by prostaglandin A_1 or dihydralazine infusions (Toppozada et al). 1991;164:1229-32
The N-terminal and C-terminal portions of the atrial natriuretic factor prohormone increase during preeclampsia (Merkouris et al). 1991;164:1197-202
Preeclampsia as the great imposter (Goodlin). 1991;164:1577-81
The relationship between autoantibodies and intrauterine growth retardation in hypertensive disorders of pregnancy (El-Roeiy et al). 1991;164:1253-61

Pregnancy complications, hematologic
Anemia and spontaneous preterm birth (Klebanoff et al). 1991;164:59-63
Does unexplained second-trimester (15 to 20 weeks' gestation) maternal serum α-fetoprotein elevation presage adverse perinatal outcome? (Simpson et al). 1991;164:829-36
Mechanisms of hemolysis and anemia associated with acute antepartum pyelonephritis (Cox et al). 1991;164:587-90
The natural history of HELLP syndrome: patterns of disease progression and regression (Martin et al). 1991;164:1500-13
Quantitative and qualitative platelet abnormalities during pregnancy (How et al). 1991;164:92-8
Should routine liver biopsy be done for the definite diagnosis of acute fatty liver of pregnancy? (Minakami et al) (Letter); (Barton and Sibai) (Reply). 1991;164:1690-1

Pregnancy complications, infectious
Amniotic fluid glucose and intraamniotic infection (Kirshon et al). 1991;164:818-20
Chlamydia trachomatis infection during pregnancy (McGregor and French). 1991;164:xx5
Cost-effectiveness of prenatal testing for *Chlamydia trachomatis* (Nettleman and Bell). 1991;164:1289-94
Cytomegalovirus infection (Hershey). 1991;164:1687 (Letter)
Fetal death associated with measles virus infection of the placenta (Moroi et al). 1991;164:1107-8
Incidence of genital herpes simplex virus at the time of delivery in women with known risk factors (Catalano et al). 1991;164:1303-6
Intraamniotic detection of *Chlamydia trachomatis* deoxyribonucleic acid sequences by polymerase chain reaction (Pao et al). 1991;164:1295-9
Intrauterine transfusion treatment of nonimmune hydrops fetalis secondary to human parvovirus B19 infection (Sahakian et al). 1991;164:1090-1
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Panty hose–pants disease (Turner). 1991;164:1366 (Letter)
Parvovirus transmission concerns (Donnenfeld and Schick-Boschetto) (Letter); (Rodis) (Reply). 1991;164:1363-4
Pharmacokinetics of acyclovir in the term human pregnancy and neonate (Frenkel et al). 1991;164:569-76
Progress in pathogenesis and management of clinical intraamniotic infection (Gibbs and Duff). 1991;164:1317-26 (Curr. dev.)
Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42
Recurrent herpes gestationis with postpartum flare: a case report (Baxi et al). 1991;164:778-80
Successful antepartum treatment of listeriosis (Kalstone). 1991;164:57-8

Pregnancy complications, neoplastic
Endodermal sinus tumor of the ovary during pregnancy: a case report (van der Zee et al). 1991;164:504-6
Lymphocytic adenohypophysitis: a pituitary mass lesion occurring in pregnancy (Feigenbaum et al). 1991;164:1549-55

Pregnancy in diabetes
Cardiac function in fetuses of type I diabetic mothers (Rizzo et al). 1991;164:837-43
The clinical utility of maternal body mass index in pregnancy (Wolfe et al). 1991;164:1306-10
Glucose challenge testing in pregnancy (Neilson et al). 1991;164:1673-9
Maternal postprandial glucose levels and infant birth weight: the Diabetes in Early Pregnancy Study (Jovanovic-Peterson et al). 1991;164:103-11
Reproducibility of the oral glucose tolerance test in pregnancy (Harlass et al). 1991;164:564-8
Transient postpartum diabetes insipidus (Raziel et al). 1991;164:616-8

Pregnancy outcome
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33

Chlamydial infection and pregnancy outcome (Forster et al) (Letter); (Ryan) (Reply). 1991;164:234
Cocaine and the use of alcohol and other drugs during pregnancy (Streissguth et al). 1991;164:1239-43
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7
Comparative efficacy of umbilical arterial Doppler indices for predicting adverse perinatal outcome (Maulik et al). 1991;164:1434-40
Comparison of associated high-risk factors and perinatal outcome between symmetric and asymmetric fetal intrauterine growth retardation (Lin et al). 1991;164:1535-42
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
Does unexplained second-trimester (15 to 20 weeks' gestation) maternal serum α-fetoprotein elevation presage adverse perinatal outcome? (Simpson et al). 1991;164:829-36
Electronic fetal heart monitoring, auscultation, and neonatal outcome (Ellison et al). 1991;164:1281-9
Glucose challenge testing in pregnancy (Neilson et al). 1991;164:1673-9
Hospital setting and fetal death during labor among women at low risk (Albers and Savitz). 1991;164:868-73
Intravenous immunoglobulin treatment of recurrent pregnancy loss and antiphospholipid antibodies (Orvieto et al). 1991;164:1687-8 (Letter)
Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33
Methotrexate treatment of ectopic gestation and reproductive outcome (Egarter) (Letter); (Stovall et al) (Reply). 1991;164:698-700
Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero (Laros et al). 1991;164:1657-65

Pregnancy proteins
Human placenta expresses endothelin gene and corresponding protein is excreted in urine in increasing amounts during normal pregnancy (Benigni et al). 1991;164:844-8

Pregnancy related mortality; *see* **Maternal mortality**

Pregnancy trimester, first
First-trimester transvaginal ultrasonographic screening: incidence of structural anomalies (Rottem) (Letter); (Cullen) (Reply). 1991;164:933
Steroid-responsive nephrotic syndrome with renal insufficiency in the first trimester of pregnancy (Uribe et al). 1991;164:568-9
Transvaginal color Doppler imaging in the assessment of uteroplacental blood flow in the normal first-trimester pregnancy (Jaffe and Warsof). 1991;164:781-5
Transvaginal ultrasonographic definition of the central nervous system in the first and early second trimesters (Timor-Tritsch et al). 1991;164:497-503

Pregnancy trimester, second
Does unexplained second-trimester (15 to 20 weeks' gestation) maternal serum α-fetoprotein elevation presage adverse perinatal outcome? (Simpson et al). 1991;164:829-36
Fetal choroid plexus cysts in the second trimester of pregnancy: a cause for concern (Platt et al). 1991;164:1652-6
Frontothalamic measurement in the second trimester of pregnancy (Crade et al). 1991;164:704-5 (Letter)
Transvaginal ultrasonographic definition of the central nervous system in the first and early second trimesters (Timor-Tritsch et al). 1991;164:497-503
The transverse cerebellar diameter in the second trimester is unaffected by Down syndrome (Hill et al). 1991;164:101-3

Pregnancy trimester, third
Does unexplained second-trimester (15 to 20 weeks' gestation) maternal serum α-fetoprotein elevation presage adverse perinatal outcome? (Simpson et al). 1991;164:829-36
Position change and central hemodynamic profile during normal third-trimester pregnancy and post partum (Clark et al). 1991;164:883-7

Premature labor; *see* **Labor, premature**

Premature rupture of membranes; *see* **Fetal membranes, premature rupture**

Premature separation of placenta; *see* **Placenta**

Prematurity; *see* **Infant, premature**

Premenopause; *see* **Menopause**

Prenatal care
The biologic and social consequences of perinatal cocaine use in an inner-city population: results of an anonymous cross-sectional study (McCalla et al). 1991;164:625-30
Cost-effectiveness of prenatal testing for *Chlamydia trachomatis* (Nettleman and Bell). 1991;164:1289-94

Prenatal diagnosis
Evaluation of an aneurysm of the vein of Galen in utero by pulsed and color Doppler ultrasonography (Ishimatsu et al). 1991;164:743-4
Investigation of placental circulations by color Doppler ultrasonography (Jauniaux et al). 1991;164:486-8
Prenatal diagnosis of myotonic muscular dystrophy with linked deoxyribonucleic acid probes (Milunsky et al). 1991;164:751-5
Webster should not affect prenatal diagnosis (Barr et al) (Letter); (Chavkin and Rosenfield) (Reply). 1991;164:706-7

Prenatal records; *see* **Medical records**

Prenatal ultrasonics; *see* **Ultrasonography, prenatal**

Presidential address
Presidential address. 1991;164:722-8, 1401-8, 1543-8

Preterm infant; *see* **Infant, premature**

Preterm labor; *see* **Labor, premature**

Preterm rupture of membranes; *see* **Fetal membranes, premature rupture**

Preventive health services
Prevention of preterm birth in high-risk patients: the role of education and provider contact versus home uterine monitoring (Dyson et al). 1991;164:756-62

Progestational hormones, synthetic
Bleeding patterns during continuous combined estrogen-progestogen therapy (Marslew et al). 1991;164:1163-8

Progesterone
Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50
The induction of premature luteolysis in normal women—follicular phase luteinizing hormone secretion and corpus luteum function in the subsequent cycle (Soules et al). 1991;164:989-96
Regulation of the immune response to *Candida albicans* by monocytes and progesterone (Kalo-Klein and Witkin). 1991;164:1351-4

Progesterone—cont'd
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94

Progestogen; *see* **Progestational hormones, synthetic**

Prognosis
Assessment of current International Federation of Gynecology and Obstetrics staging of vulvar carcinoma relative to prognostic factors for survival (A Gynecologic Oncology Group Study) (Homesley et al). 1991;164:997-1004

Prolactin
A selective serotonin reuptake inhibitor, fluoxetine hydrochloride, modulates the pulsatile release of prolactin in postmenopausal women (Urban and Veldhuis). 1991;164:147-52
Ten-year follow-up of patients with secondary amenorrhea and normal prolactin (Davajan et al). 1991;164:1666-72

Prolonged rupture of membranes; *see* **Fetal membranes**

Prophylactic antimicrobials; *see* **Antibiotics**

Propranolol
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7

Prostaglandin E2; *see* **Dinoprostone**

Prostaglandins
Effect of low-dose aspirin on vascular refractoriness in angiotensin-sensitive primigravid women (Wallenburg et al). 1991;164:1169-73

Prostaglandins A, synthetic
Management of severe preeclampsia detected in early labor by prostaglandin A_1 or dihydralazine infusions (Toppozada et al). 1991;164:1229-32

Prostanoic acids
Decreased levels of polyunsaturated fatty acids in preeclampsia (Wang et al). 1991;164:812-8

Protein C
Complexes of activated protein C with α_1-antitrypsin in normal pregnancy and in severe preeclampsia (España et al). 1991;164:1310-6

Proteinuria
The N-terminal and C-terminal portions of the atrial natriuretic factor prohormone increase during preeclampsia (Merkouris et al). 1991;164:1197-202

Puerperal disorders
Recurrent herpes gestationis with postpartum flare: a case report (Baxi et al). 1991;164:778-80
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Kool). 1991;164:701-2 (Letter)
Transient postpartum diabetes insipidus (Raziel et al). 1991;164:616-8

Puerperium
Position change and central hemodynamic profile during normal third-trimester pregnancy and post partum (Clark et al). 1991;164:883-7
Recurrent herpes gestationis with postpartum flare: a case report (Baxi et al). 1991;164:778-80

Pulmonary artery
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Kool). 1991;164:701-2 (Letter)

Pulmonary edema, animal
Dose effects of antenatal corticosteroids for induction of lung maturation in preterm rabbits (Tabor et al). 1991;164:675-81

Pulmonary surfactants
Dose effects of antenatal corticosteroids for induction of lung maturation in preterm rabbits (Tabor et al). 1991;164:675-81
Inhibition of pulmonary surfactant function by meconium (Moses et al). 1991;164:477-81

Pulsed ultrasonography; *see* **Ultrasonography**

Purpura, thrombocytopenic
Fetal subdural hematoma before labor (Gunn and Becroft) (Letter); (Myers) (Reply). 1991;164:934-5

Pyelonephritis
Mechanisms of hemolysis and anemia associated with acute antepartum pyelonephritis (Cox et al). 1991;164:587-90
Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80

Q

Quality assurance, health care
Maternal serum α-fetoprotein screening: further consideration of low-volume testing (Strickland et al). 1991;164:711-4 (Clin. opinion)
Stratification and standards: a quality assurance perspective (Zinberg). 1991;164:722-8 (Pres. address)

Quinolinones
Antimicrobials in the 1990s: expanded options for effective patient care—summary (Faro). 1991;164:1399-400
Patient costs for prophylaxis and treatment of obstetric and gynecologic surgical infections (Stein). 1991;164:1377-80

R

Radiation injuries
Management of radionecrosis of the vulva and distal vagina (Roberts et al). 1991;164:1235-8

Radical hysterectomy; *see* **Hysterectomy**

Radiographic magnification
Improved mammographic accuracy (Pillsbury et al). 1991;164:1643-6

Radionecrosis; *see* **Radiation injuries**

Rape
Cervical findings in rape victims (Slaughter and Brown). 1991;164:528-9

Rats, inbred strains
Pharmacokinetics of pentamidine in Sprague-Dawley rats in late pregnancy (Little et al). 1991;164:927-30

Receptors, adrenergic
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7

Receptors, adrenergic, beta
Comparison of pulsatile and continuous ritodrine administration: effects on uterine contractility and β-adrenergic receptor cascade (Caritis et al). 1991;164:1005-12

Receptors, antigen, T-cell
Intradecidual T lymphocytes lack T-cell receptors (Dietl et al). 1991;164:702 (Letter)

Receptors, epidermal growth factor-urogastrone
Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. I. Correlation of receptor expression with prognostic factors in patients with ovarian cancer (Berchuck et al). 1991;164:669-74

Epidermal growth factor receptor expression in normal ovarian epithelium and ovarian cancer. II. Relationship between receptor expression and response to epidermal growth factor (Rodriguez et al). 1991;164:745-50

Receptors, estradiol

Fibrocystic disease of the breast in premenopausal women: histohormonal correlation and response to luteinizing hormone–releasing hormone analog treatment (Monsonego et al). 1991;164:1181-9

Receptors, estrogen

Estrogen receptors in the external anal sphincter (Haadem et al). 1991;164:609-10

Recombinant tissue plasminogen activator; *see* **Plasminogen activator, tissue-type**

Rectum, surgery

Posterior colporrhaphy and perineorrhaphy: separate and distinct operations (Nichols). 1991;164:714-21 (Clin. opinion)

Regression analysis

Effect of subject height on the result for the fifty-gram oral glucose tolerance test (Phillipou). 1991;164:698 (Letter)

Renal failure, acute; *see* **Kidney failure, acute**

Renal insufficiency; *see* **Kidney failure, acute**

Renin-angiotensin system

Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50

Reproducibility of results

Reproducibility of the oral glucose tolerance test in pregnancy (Harlass et al). 1991;164:564-8

Research design

Antepartum testing in the hypertensive patient: when to begin (Pircon et al). 1991;164:1563-70

Residency training; *see* **Internship and residency**

Respiratory distress syndrome

Fetal thyroid-stimulating hormone response to maternal administration of thyrotropin-releasing hormone (Thorpe-Beeston et al). 1991;164:1244-5

Respiratory distress syndrome, adult

Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80

Respiratory insufficiency

Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80

Restriction fragment length polymorphism

Restriction fragment length polymorphism analysis to study the genetic origin of complete hydatidiform mole (Ko et al). 1991;164:901-6

Retained placenta; *see* **Placenta**

Rh isoimmunization

Rh immune globulin prophylaxis for threatened abortions (Kuller) (Letter); (Dayton et al) (Reply). 1991;164: 703-4

Risk factors

Comparison of associated high-risk factors and perinatal outcome between symmetric and asymmetric fetal intrauterine growth retardation (Lin et al). 1991;164:1535-42

Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9

Pregnancy-related mortality in New York City, 1980 to 1984: causes of death and associated risk factors (Syverson et al). 1991;164:603-8

Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80

Reduction of cardiovascular disease–related mortality among postmenopausal women who use hormones: evidence from a national cohort (Wolf et al). 1991;164:489-94

Reproductive factors and risk of endometrial cancer (Parazzini et al). 1991;164:522-7

Small-for-gestational-age birth: maternal predictors and comparison with risk factors of spontaneous preterm delivery in the same cohort (Abrams and Newman). 1991;164:785-90

Risk management

Alternative liability insurance: a physician-owned captive insurance company (Lee). 1991;164:1680-5

Ritodrine

Comparison of pulsatile and continuous ritodrine administration: effects on uterine contractility and β-adrenergic receptor cascade (Caritis et al). 1991;164:1005-12

Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero (Laros et al). 1991;164:1657-65

Randomized comparative trial of indomethacin and ritodrine for the long-term treatment of preterm labor (Besinger et al). 1991;164:981-8

ROC curve

Comparative efficacy of umbilical arterial Doppler indices for predicting adverse perinatal outcome (Maulik et al). 1991;164:1434-40

Roster

Roster of American obstetric and gynecologic societies. 1991;164:238-9

Routine diagnostic tests; *see* **Diagnostic tests**

RU 486; *see* **Mifepristone**

S

Sacrocervicopexy; *see* **Fascia lata, transplantation**

Salpingitis

Chlamydia trachomatis: female pelvic infection (Faro). 1991;164:1767-70

Diagnosis and laparoscopic grading of acute salpingitis (Soper). 1991;164:1370-6

Genital chlamydial infections: epidemiology and reproductive sequelae (Cates and Wasserheit). 1991;164:1771-81

A randomized trial of ofloxacin versus cefoxitin and doxycycline in the outpatient treatment of acute salpingitis (Wendel et al). 1991;164:1390-6

Scanning electron microscopy; *see* **Microscopy, electron, scanning**

Sclerotherapy

Endoscopic sclerotherapy in extrahepatic portal hypertension in pregnancy (Pauzner et al). 1991;164:152-3

Second trimester of pregnancy; *see* **Pregnancy trimester, second**

Sedation; *see* **Hypnotics and sedatives**

Seizures

Antiepileptic medication in pregnancy: late effects on the children's central nervous system development (van der Pol et al). 1991;164:121-8

Effects of acute hypermagnesemia on the threshold for lidocaine-induced seizures in the rat (Choi et al). 1991;164:693-7

Serotonin, antagonists and inhibitors

A selective serotonin reuptake inhibitor, fluoxetine hydrochloride, modulates the pulsatile release of prolactin in

Serotonin, antagonists and inhibitors—cont'd
postmenopausal women (Urban and Veldhuis). 1991;164:147-52
Sex behavior
Impact of tubal sterilization and vasectomy on female marital sexuality: results of a controlled longitudinal study (Shain et al). 1991;164:763-71
Sex education
Menstrual mythology and sources of information about menstruation (Cumming et al). 1991;164:472-6 (Clin. opinion)
Sex preselection
Attitudes on the ethics of abortion, sex selection, and selective pregnancy termination among health care professionals, ethicists, and clergy likely to encounter such situations (Evans et al). 1991;164:1092-9
Sexuality; *see* **Sex behavior**
Sexually transmitted diseases; *see also specific diseases*
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Shock
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Kool). 1991;164:701-2 (Letter)
Small-for-gestational-age birth; *see* **Infant, small for gestational age**
Smoking
Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9
Smooth muscle; *see* **Muscle, smooth**
Society of Perinatal Obstetricians
Program of the eleventh annual meeting of the Society of Perinatal Obstetricians. 1991;164:241-466
Socioeconomic factors
Prevalence of acquired immunodeficiency syndrome detected during prenatal care of population of low socioeconomic status (Porto) (Letter); (Barton) (Reply). 1991;164:705-6
Sodium
Characterization of sodium channels in cultured human uterine smooth muscle cells (Young and Herndon-Smith). 1991;164:175-81
Sperm; *see* **Spermatozoa**
Sperm count
The importance of the postcoital test (Check) (Letter); (Grimes and Griffith) (Reply). 1991;164:932-3
Spermatozoa
Antisperm antibodies to sperm surface antigens in women with genital tract infection (Cunningham et al). 1991;164:791-6
Multinuclear spermatozoa associated with polyploidy (Parikh et al). 1991;164:128-9
Pregnancy rates after peritoneal ovum-sperm transfer (Coulam et al). 1991;164:1447-52
Prospective analysis of sperm-oocyte fusion and reactive oxygen species generation as criteria for the diagnosis of infertility (Aitken et al). 1991;164:542-51
Recurrent failure of in vitro fertilization: role of the hemizona assay in the sequential diagnosis of specific sperm-oocyte defects (Oehninger et al). 1991;164:1210-5
Spina bifida cystica
Tables for estimation of individual risks of fetal neural tube and ventral wall defects, incorporating prior probability, maternal serum α-fetoprotein levels, and ultrasonographic examination results (Thornton et al). 1991;164:154-60
Spouse abuse
Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9
Sprague-Dawley rats; *see* **Rats, inbred strains**
Squamous cell carcinoma; *see* **Carcinoma, squamous cell**
Staging of neoplasms; *see* **Neoplasm staging**
Sterile water blocks; *see* **Injections, intradermal**
Sterilization, tubal
Impact of tubal sterilization and vasectomy on female marital sexuality: results of a controlled longitudinal study (Shain et al). 1991;164:763-71
Steroids
Ovarian response in superovulated cycles after suppression with oral contraceptive steroids (Burry et al). 1991;164:1592-6
Spontaneous and steroid-induced recurrence of endometriosis after suppression by a gonadotropin-releasing hormone antagonist in the rat (Sharpe et al). 1991;164:187-94
Steroid-responsive nephrotic syndrome with renal insufficiency in the first trimester of pregnancy (Uribe et al). 1991;164:568-9
Stillbirth; *see* **Fetal death**
Streptococcus agalactiae
Group B streptococcal disease (Matorras et al) (Letter); (Silver and Gibbs) (Reply). 1991;164:1152-3
Streptococcus* group B**; *see* ***Streptococcus agalactiae
Subdural hematoma; *see* **Hematoma, subdural**
Substance abuse
The biologic and social consequences of perinatal cocaine use in an inner-city population: results of an anonymous cross-sectional study (McCalla et al). 1991;164:625-30
Cocaine and the use of alcohol and other drugs during pregnancy (Streissguth et al). 1991;164:1239-43
Cocaine directly augments the α-adrenergic contractile response of the pregnant rabbit uterus (Hurd et al). 1991;164:182-7
Cocaine in pregnancy: the effect of maternal administration of cocaine on the maternal and fetal pituitary-adrenal axes (Owiny et al). 1991;164:658-63
Drug abuse and other risk factors for physical abuse in pregnancy among white non-Hispanic, black, and Hispanic women (Berenson et al). 1991;164:1491-9
Superstitions
Menstrual mythology and sources of information about menstruation (Cumming et al). 1991;164:472-6 (Clin. opinion)
Surface antigens; *see* **Antigens, surface**
Surfactants, pulmonary; *see* **Pulmonary surfactants**
Survival
Assessment of current International Federation of Gynecology and Obstetrics staging of vulvar carcinoma relative to prognostic factors for survival (A Gynecologic Oncology Group Study) (Homesley et al). 1991;164:997-1004
Stage IB squamous cell cancer of the cervix: clinicopathologic features related to survival (Hopkins and Morley). 1991;164:1520-9
Sutures
Suture entrapment and secondary ureteral obstruction (Stanhope et al). 1991;164:1513-9

Sympathomimetics
The effects of indomethacin and a β-sympathomimetic agent on the fetal ductus arteriosus during treatment of premature labor: a randomized double-blind study (Eronen et al). 1991;164:141-6
Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero (Laros et al). 1991;164:1657-65

T

T-cell receptors; *see* **Receptors, antigen, T-cell**
T-lymphocytes
Intradecidual T lymphocytes lack T-cell receptors (Dietl et al). 1991;164:702 (Letter)
Temporal arteritis
A case report of giant cell arteritis of the uterus and adnexa (Summers et al). 1991;164:540-2
Teratoma
Gliomatosis peritonei with malignant transformation: a case report and review of the literature (Shefren et al). 1991;164:1617-21
Terbutaline
Outcome of very-low-birth-weight infants exposed to β-sympathomimetics in utero (Laros et al). 1991;164:1657-65
Tetracycline
The effect of tetracycline on levels of oral contraceptives (Murphy et al). 1991;164:28-33
Thermogenesis; *see* Body temperature
Third trimester of pregnancy; *see* **Pregnancy trimester, third**
Threatened abortions; *see* **Abortion, threatened**
Thrombocytopenia
Fetal-neonatal thrombocytopenia: Mode of delivery? (Levy) (Letter); (Burrows and Kelton) (Reply). 1991;164:1362-3
Quantitative and qualitative platelet abnormalities during pregnancy (How et al). 1991;164:92-8
Thrombocytopenic purpura; *see* **Purpura, thrombocytopenic**
Thromboembolectomy; *see* **Thrombosis**
Thrombosis
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Kool). 1991;164:701-2 (Letter)
Thromboxanes
Decreased levels of polyunsaturated fatty acids in preeclampsia (Wang et al). 1991;164:812-8
Thyroid gland
The effects of iodoprophylaxis on thyroid size during pregnancy (Romano et al). 1991;164:482-5
Thyroid-stimulating hormone; *see* **Thyrotropin**
Thyrotropin
Fetal thyroid-stimulating hormone response to maternal administration of thyrotropin-releasing hormone (Thorpe-Beeston et al). 1991;164:1244-5
Thyrotropin-releasing hormone
Fetal thyroid-stimulating hormone response to maternal administration of thyrotropin-releasing hormone (Thorpe-Beeston et al). 1991;164:1244-5
Tissue culture
Effect of progesterone on renin secretion in endometrial stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50
Tissue plasminogen activator; *see* **Plasminogen activator, tissue-type**
Tobacco use; *see* **Smoking**
Tobramycin
Combination antimicrobial therapy in the treatment of acute pelvic inflammatory disease (Landers et al). 1991;164:849-58
Tocolysis
Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity (Romero et al). 1991;164:859-62
Prevention of preterm birth in high-risk patients: the role of education and provider contact versus home uterine monitoring (Dyson et al). 1991;164: 756-62
Pulmonary injury associated with antepartum pyelonephritis: Can patients at risk be identified? (Towers et al). 1991;164:974-80
Randomized comparative trial of indomethacin and ritodrine for the long-term treatment of preterm labor (Besinger et al). 1991;164:981-8
Tokodynamometry; *see* **Cardiotocography**
Torsion
Fetal ovarian cysts: prenatal ultrasonographic detection and postnatal evaluation and treatment (Meizner et al). 1991;164:874-8
Ovarian neoplasms and the risk of adnexal torsion (Sommerville et al). 1991;164:577-8
Trachoma virus; *see* ***Chlamydia trachomatis***
Tranexamic acid
A comparison of flurbiprofen, tranexamic acid, and a levonorgestrel-releasing intrauterine contraceptive device in the treatment of idiopathic menorrhagia (Milsom et al). 1991;164:879-83
Transabdominal cerclage; *see* **Cervix incompetence**
Transactions
Transactions of the fifty-eighth annual meeting of the Central Association of Obstetricians and Gynecologists. 1991;164:1401-542
Transactions of the fifty-seventh annual meeting of the Pacific Coast Obstetrical and Gynecological Society. 1991;164:1543-685
Transactions of the ninth annual meeting of the American Gynecological and Obstetrical Society. 1991;164:939-1071
Transmission electron microscopy; *see* **Microscopy, electron**
Transplantation, autologous
Fertility retention in the patient with genital prolapse (Nichols). 1991;164:1155-8 (Clin. opinion)
Transplantation, homologous
Transplantation of fetal cells (Crombleholme et al). 1991;164:218-30 (Curr. dev.)
Transvaginal ultrasonography; *see* **Ultrasonography**
Transverse cerebellar diameter; *see* **Fetal development**
Treatment refusal
Outpatient sedation: an essential addition to gynecologic care for persons with mental retardation (Rosen et al). 1991;164:825-8
Trial of labor
Vaginal birth after cesarean section: the impact of patient resistance to a trial of labor (Joseph et al). 1991;164: 1441-7
Triplets
Cross-sectional analysis of triplet birth weight (Jones et al). 1991;164:135-40
Trisomy
Fetal choroid plexus cysts in the second trimester of pregnancy: a cause for concern (Platt et al). 1991;164:1652-6
Trophoblast
Effect of progesterone on renin secretion in endometrial

Trophoblast—cont'd
stromal, chorionic trophoblast, and mesenchymal monolayer cultures (Shah et al). 1991;164:1145-50
Forskolin and methotrexate induce an intermediate trophoblast phenotype in cultured human choriocarcinoma cells (Taylor et al). 1991;164:204-10
Immunohistochemical localization of gonadotropin-releasing hormone during implantation in the New Zealand White rabbit (Bergh et al). 1991;164:1127-31
Trophoblastic tumor
Prognostic factors in gestational trophoblastic tumors: a proposed new scoring system based on multivariate analysis (Lurain et al). 1991;164:611-6
A prospective genetic study of complete and partial hydatidiform moles (Lawler et al). 1991;164:1270-7
Tubal pregnancy; *see* **Pregnancy, tubal**
Tubal sterilization; *see* **Sterilization, tubal**
Tuboovarian abscess; *see* **Adnexitis**
Tumor antigens; *see* **Antigens, neoplasm**
Tumor markers, biological
Serum interleukin-6 levels correlate with disease status in patients with epithelial ovarian cancer (Berek et al). 1991;164:1038-43
Twin transfusion syndrome; *see* **Fetofetal transfusion**
Twins
Fetal vibratory acoustic stimulation in twin gestations with simultaneous fetal heart rate monitoring (Sherer et al). 1991;164:1104-6
Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33

U

Ultrasonography
Dissection of the cardinal ligament in radical hysterectomy for cervical cancer with emphasis on the lateral ligament (Yabuki et al). 1991;164:7-14 (Clin. opinion)
Endometrial thickness as measured by endovaginal ultrasonography for identifying endometrial abnormality (Granberg et al). 1991;164:47-52
Hysterosalpingography with color Doppler ultrasonography (Peters and Coulam). 1991;164:1530-4
Improved mammographic accuracy (Pillsbury et al). 1991;164:1643-6
Ultrasonography in the diagnosis of gynecologic disorders (Willson). 1991;164:1064-71
Ultrasonography, prenatal
Cardiac function in fetuses of type I diabetic mothers (Rizzo et al). 1991;164:837-43
The clinical implications of subchorionic placental lucencies (Katz et al). 1991;164:99-100
The current status of maternal and fetal blood flow velocimetry (Low). 1991;164:1049-63
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
Diastolic circulatory dynamics in the presence of elevated placental resistance and retrograde diastolic flow in the umbilical artery: a Doppler echographic study in lambs (Fouron et al). 1991;164:195-203
Evaluation of an aneurysm of the vein of Galen in utero by pulsed and color Doppler ultrasonography (Ishimatsu et al). 1991;164:743-4
Evaluation of changes in umbilical blood flow in the fetal lamb by Doppler waveform analysis (Schmidt et al). 1991;164:1118-26
Fetal ovarian cysts: prenatal ultrasonographic detection and postnatal evaluation and treatment (Meizner et al). 1991;164:874-8
First-trimester transvaginal ultrasonographic screening: incidence of structural anomalies (Rottem) (Letter); (Cullen) (Reply). 1991;164:933
Follow-up of elevated maternal serum α-fetoprotein levels: Ultrasonography only or amniocentesis? (Whitehead et al). 1991;164:1688-9 (Letter)
Frontothalamic measurement in the second trimester of pregnancy (Crade et al). 1991;164:704-5 (Letter)
In utero diagnosis and management of fetal subdural hematoma (Rotmensch et al). 1991;164:1246-8
Investigation of placental circulations by color Doppler ultrasonography (Jauniaux et al). 1991;164:486-8
Is pulsed Doppler velocimetry useful in the management of multiple-gestation pregnancies? (Gaziano et al). 1991;164:1426-33
The relationships among umbilical artery velocimetry, fetal biophysical profile, and placental inflammation in preterm premature rupture of the membranes (Fleming et al). 1991;164:38-41
The role of the transcerebellar view in the detection of fetal central nervous system anomaly (Hill et al). 1991;164:1220-4
The roles of ultrasonography and amniocentesis in evaluation of elevated maternal serum α-fetoprotein (Lindfors et al). 1991;164:1571-6
Screening and detection of congenital malformation (Pitkin). 1991;164:1045-8
Tables for estimation of individual risks of fetal neural tube and ventral wall defects, incorporating prior probability, maternal serum α-fetoprotein levels, and ultrasonographic examination results (Thornton et al). 1991;164:154-60
Transvaginal color Doppler imaging in the assessment of uteroplacental blood flow in the normal first-trimester pregnancy (Jaffe and Warsof). 1991;164:781-5
Transvaginal ultrasonographic definition of the central nervous system in the first and early second trimesters (Timor-Tritsch et al). 1991;164:497-503
The transverse cerebellar diameter in the second trimester is unaffected by Down syndrome (Hill et al). 1991;164:101-3
Ultrasonography in obstetrics and gynecology: the state of the art in 1990—panel discussion. 1991;164:1044
Umbilical artery blood flow velocity waveforms during variable decelerations of the fetal heart rate (Weiss et al). 1991;164:534-40
Venous Doppler ultrasonography in the fetus with nonimmune hydrops (Gudmundsson et al). 1991;164:33-7
Umbilical arteries
Comparative efficacy of umbilical arterial Doppler indices for predicting adverse perinatal outcome (Maulik et al). 1991;164:1434-40
Determinants of perinatal outcome in pregnancy-induced hypertension with absence of umbilical artery end-diastolic frequencies (Fairlie et al). 1991;164:1084-9
Diastolic circulatory dynamics in the presence of elevated placental resistance and retrograde diastolic flow in the umbilical artery: a Doppler echographic study in lambs (Fouron et al). 1991;164:195-203

Neonatal complications at term as related to the degree of umbilical artery acidemia (Winkler et al). 1991;164:637-41
The relationships among umbilical artery velocimetry, fetal biophysical profile, and placental inflammation in preterm premature rupture of the membranes (Fleming et al). 1991;164:38-41
Umbilical arterial and venous acid-base and blood gas values and the effect of chorioamnionitis on those values in a cohort of preterm infants (Hankins et al). 1991;164:1261-4
Umbilical artery blood flow velocity waveforms during variable decelerations of the fetal heart rate (Weiss et al). 1991;164:534-40

Umbilical blood; *see* **Fetal blood**

Umbilical blood sampling; *see* **Fetal blood**

Umbilical cord
Intraumbilical injection of oxytocin (Chestnut) (Letter); (Golan) (Reply). 1991;164:702-3
Umbilical cord ulceration and intestinal atresia: A new association? (Bendon et al). 1991;164:582-6

Umbilical cord blood; *see* **Fetal blood**

Umbilical veins
Umbilical arterial and venous acid-base and blood gas values and the effect of chorioamnionitis on those values in a cohort of preterm infants (Hankins et al). 1991;164:1261-4
Umbilical vein administration of oxytocin for the management of retained placenta: Is it effective? (Huber et al). 1991;164:1216-9
Venous Doppler ultrasonography in the fetus with nonimmune hydrops (Gudmundsson et al). 1991;164:33-7

Ureaplasma
Antepartum cultures for *Ureaplasma urealyticum* are not useful in predicting pregnancy outcome (Carey et al). 1991;164:728-33
A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery (Eschenbach et al). 1991;164:734-42

Ureteral obstruction
Suture entrapment and secondary ureteral obstruction (Stanhope et al). 1991;164:1513-9

Urethritis
The clinical experience with ofloxacin in the treatment of sexually transmitted diseases (Corrado). 1991;164:1396-9
Genital chlamydial infections: epidemiology and reproductive sequelae (Cates and Wasserheit). 1991;164:1771-81

Urinary incontinence, stress
A method for safer urinary incontinence surgery (Gallaspy). 1991;164:1151 (Letter)
Simplified urethrocystovaginal suspension for stress urinary incontinence (Toan) (Letter); (Varner) (Reply). 1991;164:1689-90

Urinary tract
Urinary tract dilatation in pregnancy (Brown). 1991;164:642-3

Urinary tract infections
New directions in the diagnosis and therapy of urinary tract infections (Powers). 1991;164:1387-9

Uterine contraction
Antepartum testing in the hypertensive patient: when to begin (Pircon et al). 1991;164:1563-70
Comparison of pulsatile and continuous ritodrine administration: effects on uterine contractility and β-adrenergic receptor cascade (Caritis et al). 1991;164:1005-12
Dilatation despite cervical cerclage: a diagnostic pitfall (Jacquemyn and Buytaert). 1991;164:1686-7 (Letter)
Magnesium sulfate–induced relaxation of uterine arteries from pregnant and nonpregnant patients (Nelson and Suresh). 1991;164:1344-50

Uterine hemorrhage
Hormonal inhibition of the endometrium for resectoscopic endometrial ablation (Brooks et al). 1991;164:1601-8

OB/GYN PARTNERSHIP OPPORTUNITY

Obstetrician/Gynecologist needed to join with a two-physician practice that is starting on the campus of ALBERT EINSTEIN MEDICAL CENTER. A new $6 million labor and delivery suite currently is under construction. A brand new fully-equipped office space is available. The two physicians you will be joining are clinically outstanding and have an established referral base.

Located in the northern part of Philadelphia, you are offered the challenges of a 600-Bed, Level III teaching Hospital that is centrally located to nearby cultural and recreational areas.

We offer a competitive compensation and benefit package. If you like to teach, that opportunity is available through the Albert Einstein Ob/Gyn Residency program.

Applicants must be Board-Certified or an active candidate for board certification.

Send Curriculum Vitae to:
Sze-ya Yeh, M.D.
Chairman, Dept. of Ob/Gyn
Suite 410, Klein Bldg.
Albert Einstein Medical Center
5401 Old York Rd.
Philadelphia, Pennsylvania, 19141
(215) 456-6993

of Tompkins County

THE DEPARTMENT OF OBSTETRICS AND GYNECOLOGY UNIVERSITY OF WISCONSIN MEDICAL SCHOOL

is seeking applicants for four (4) full-time faculty positions for a new women's health center and academic program at its Milwaukee Clinical Campus.

Sinai Samaritan Medical Center has recently consolidated its obstetrical and gynecological services in a redesigned facility in downtown Milwaukee. The department supports a residency program, the largest perinatal service in Wisconsin (5500 deliveries), consultative ultrasound, genetic and infectious disease programs, and reproductive/endocrine services (including an IVF program). The department is affiliated with Planned Parenthood of Wisconsin and St. Luke's Medical Center in Milwaukee.

Qualifications include board candidacy or certification in obstetrics and gynecology and a commitment to teaching residents, medical students, and clinical research. Qualifications for the four positions for GENERAL OB/GYN can take into consideration special individual interests. Special expertise of interest for the department are:

- STATEWIDE FAMILY PLANNING AND AMBULATORY CARE (Part-time medical director, Planned Parenthood)
- OPERATIVE LAPAROSCOPY, HYSTEROSCOPY
- UROGYNECOLOGY
- RESIDENCY/MEDICAL STUDENT EDUCATION
- OB/GYN ULTRASOUND

Private practice opportunities are also available in an associated offsite multispecialty clinic and all faculty members participate in a group practice at the institution. Contact:

UCLA INTERCAMPUS MEDICAL GENETICS TRAINING PROGRAM

The UCLA intercampus post-doctoral research training program in Medical Genetics utilizes the research and clinical resources of its affiliated campuses and teaching hospitals. The program is open to academically oriented applicants with the M.D., Ph.D., D.D.S. or equivalent degrees. A wide variety of research training opportunities in molecular, biochemical, immuno-, cancer, cyto-, somatic cell, population and clinical genetics are available. The program also meets all the requirements of the American Board of Medical Genetics. Clinical genetics fellowships are available at each of the affiliated hospitals. Application forms are available from David Rimoin, M.D., Ph.D., Department of Pediatrics, Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048.

MATERNAL-FETAL MEDICINE

The University of North Carolina at Chapel Hill Department of Obstetrics and Gynecology in conjunction with the Wake Medical Center, Raleigh, North Carolina, and the Wake Area Health Education Center has an opening for a board certified or active candidate perinatologist with a special interest in ultrasound and genetics. The position is in the Wake AHEC OB/GYN Department which has two full-time obstetricians and gynecologists, plus the program director who is board certified in Maternal-Fetal Medicine.

Wake Medical Center is located in Raleigh, approximately 40 minutes from Chapel Hill, and is a 560-bed comprehensive tertiary care center with over 4000 deliveries per year and a neonatal intensive care unit staffed by four neonatologists.

Excellent opportunity for research and teaching of residents and medical students rotating through Wake Medical Center at all times. Collaboration with the Maternal-Fetal Medicine Division at the University of North Carolina is encouraged and anticipated.

Academic appointment and salary dependent on training and experience.

Write or contact:

Juan L. Granados, M.D.
OB/GYN Wake AHEC Director
Wake County Medical Center
3000 New Bern Avenue
Raleigh, NC 27610
(919) 250-8535

An Equal Opportunity/Affirmative Action Employer

FACULTY POSITION
DIVISION DIRECTOR
MATERNAL-FETAL MEDICINE

- ANTENATAL UNIT
- 5500 DELIVERIES/YEAR
- PREMIER NEWBORN INTENSIVE CARE UNIT
- 7 NEONATOLOGISTS
- 24 HR. IN HOUSE OBSTETRICAL ANESTHESIA
- ULTRASOUND LAB (2 - ACUSON 128XP)
- INTERVENTIONAL SONOGRAPHIC EXPERIENCE
- AIR/GROUND TRANSPORT SYSTEM
- LARGE REFERRAL AREA
- LOW COST OF LIVING
- EXTREMELY COMPETITIVE COMPENSATION PACKAGE
- RESEARCH/GRANT OPPORTUNITIES
- TEACHING RESIDENTS & STUDENTS

The Department of Obstetrics & Gynecology at the University of Kansas School of Medicine-Wichita is accepting applications for the position of Director of the Division of Maternal-Fetal Medicine. This represents a unique opportunity to have the best features of both academic medicine and private practice.

Please send curriculum vitae to:

Daniel K. Roberts, M.D., Ph.D.
Professor & Chairman, Dept. of Ob/Gyn

NORTHERN CALIFORNIA

The Permanente Medical Group, a growing multispecialty group, is recruiting for positions in our beautiful Northern California region: the San Francisco Bay Area, Sacramento and the Central Valley.

REPRODUCTIVE ENDOCRINOLOGIST

• SAN JOSE •

We are currently seeking a Reproductive Endocrinologist to establish and run a reproductive endocrinology subdivision in the department. Duties would include the full spectrum of reproductive endocrinology, outpatient and surgical management of infertility. Fellowship certification would be preferred. The department currently has 17 physicians and is still growing. We offer a generous benefits package including full coverage malpractice insurance. San Jose has beautiful weather and excellent access to Bay Area recreational and cultural activities.

For more information, please contact: Jerome L. Nehemiah, M.D., Chief, Department of OB/GYN, The Permanente Medical Group, Inc., 260 International Circle, Dept. AJOBG, San Jose, CA 95119. or call collect (408) 972-6180. EOE

KAISER PERMANENTE

Good People. Good Medicine.

FACULTY POSITIONS IMMEDIATELY AVAILABLE

Maternal Fetal Medicine — Reproductive Endocrinology — Obstetrics/Gynecology — Urogynecology

The Department of Obstetrics and Gynecology at the University of South Dakota School of Medicine in Sioux Falls, South Dakota, a delightful city located directly on the Sioux River and serving a tri-state area and one of the best kept secrets in the Midwest, is building a full-time academic department. Qualified individuals to contribute, develop and provide leadership in all aspects of the specialty are actively being sought.

Candidates should have interests in clinical practice activities and medical education. Clinical and/or basic research opportunities are available and encouraged. An opportunity for a creative, motivated individual with a pioneer spirit.

Financial remuneration and incentives are competitive and commensurate with experience, credentials and rank. BC or BE. Position open until filled.

Please send Curriculum Vitae to: R. H. Wiebe, M.D., Professor and Chairman, Department of Obstetrics and Gynecology, University of South Dakota School of Medicine, 1100 South Euclid Avenue, Sioux Falls, SD 57117-5039, (605) 333-7327.

An Equal Opportunity/Affirmative Action Employer

OBSTETRICIAN & GYNECOLOGIST

Wyeth-Ayerst Laboratories, a leading multinational pharmaceutical/nutritional manufacturer responsible for the development of female health products, has an immediate position available in its Radnor, PA headquarters for a board certified Obstetrician and Gynecologist.

A minimum of 5 years private practice and some experience in clinical research is desired. The successful candidate will assist in the development and implementation of clinical protocols and case report forms, monitor clinical studies, interpret data and assist in medical marketing liaisons. Good communicative skills and a willingness to travel worldwide are required.

We offer competitive salaries and compensation programs in a modern, professional setting. For immediate consideration, forward your resume with salary requirements to: **Wyeth-Ayerst Laboratories, Position #172, P.O. Box 8299, Philadelphia, PA 19101.** An equal opportunity employer, M/F/H/V responses encouraged. Principals Only.

Mosby
Year Boo

Provide vital information to those who need it most...
with article reprints from Mosby–Year Book periodicals

Article reprints are your best means of distributing the information published i Mosby–Year Book's medical, dental, and nursing periodicals. These papers will enhance the value of your information programs.

Not just for authors, reprints are an effe tive tool for health care professionals, sales and marketing staffs, and advertisers.

Use reprints to:

- Train and educate your sales and marketing staff
- Support your seminar topic
- Inform your health care staff of new developments
- Reach your product users with vital information

Article reprints...another valuable service from Mosby–Year Book.

Orders (minimum of 100 copies) of all previous and future articles in Mosby–Year Book periodicals are available from the Publisher.

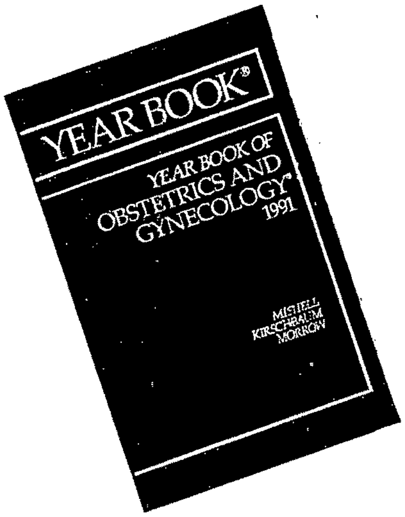
Modern medicine's answer to normal memory loss.



A lively and authoritative review of the year's best journal literature.

Let's face it. Remembering everything from the hundreds of articles you read is a herculean task. You're bound to forget a few important details. It's normal. It's healthy. But with a subscription to the *Year Book of Obstetrics and Gynecology*, it's also unnecessary.

Each year, the *Year Book of Obstetrics and Gynecology* brings you the most important articles relating to obstetrics and gynecology. The articles, chosen by our distinguished editors, are abstracted into concise one and two page summaries for quick and efficient reading. Nearly every article is accompanied by personal commentary from the editors discussing its significance to your daily practice.

The *Year Book of Obstetrics and Gynecology*— it's the best way to remember what you shouldn't forget.

☐ **Yes! I want an overview of the year's most important journal literature.**

Please send my **30-day FREE examination** copy of the *1991 Year Book of Obstetrics and Gynecology* (22118) by Daniel R. Mishell, Jr. If I decide to keep the book I'll pay $57.95 plus shipping and handling.

When you purchase a Year Book, we'll also send you an automatic notice of future volumes about two months before they publish. This system was designed for your convenience and to take up as little of your time as possible. If you do not want the Year Book, the advance notice makes it easy for you to let us know. And if you elect to receive the new Year Book, you need do nothing. We will send it on publication. No worry. No wasted motion. And, of course, every Year Book is yours to examine *free of charge* for 30 days.

The one drug test a woman can't afford to fail.

Knowing the right answers to this test can mean the difference between life and death to a woman and her unborn child. Cut it out now and give copies to all your patients, even if you don't suspect a drug problem. Even if they are not pregnant. Because if your patients don't know the right answers, now's the time to talk with them and help them to understand.

Drugs and Pregnancy: Did you know?

1. Did you know that if you use cocaine while you're pregnant, you have a much greater chance of having a miscarriage? ☐ YES ☐ NO

2. Did you know that if you use cocaine, you can pass it on to your baby through your breast milk? ☐ YES ☐ NO

3. Did you know that if you use any illicit drug while you're pregnant, there's a greater chance that you will have a low-birthweight baby? ☐ YES ☐ NO

4. Did you know that low birthweight is associated with a greater risk of infant death and mental and physical handicaps? ☐ YES ☐ NO

5. Did you know that heroin use during pregnancy increases the likelihood of stillbirth and death among newborns? ☐ YES ☐ NO

6. Did you know that if you or any of your sexual partners ever used an illicit IV drug, you may be infected with the AIDS virus (HIV), and that you can pass that virus on to your unborn child? ☐ YES ☐ NO

7. Did you know that if you use cocaine, are addicted to heroin, or are methadone-dependent, your children will be at a greater risk for sudden infant death syndrome (SIDS)? ☐ YES ☐ NO

8. Did you know that if you use barbiturates during your pregnancy you can change your child's normal patterns of growth and behavior? Your child might also suffer withdrawal symptoms for months after birth, including high-pitched crying, irritability, and sleep disturbances. ☐ YES ☐ NO

9. Is your doctor aware of all the prescription and/or illicit drugs you may be taking? ☐ YES ☐ NO

Did you know that if you have a drug problem, there are many people and resources you can turn to for help? Just ask your doctor.

✂ *Cut along dotted line, copy, and distribute to patients as you see fit.*

Fertility and Sterility, the red journal, has world-wide circulation and is highly regarded in this country and abroad. Now in its 5th decade, it publishes juried original articles of scientific excellence in clinical and laboratory research relevant to reproductive endocrinology, physiology, and immunology. Citation analysis indicates that it is among the most frequently referenced scientific journals and has one of the highest impact factors in the field of reproductive medicine. The journal is an indispensable resource to reproductive endocrinologists, obstetricians gynecologists, urologists, and basic scientists who treat and investigate the problems of fertility, sterility and physiology of reproduction.

21- and 28-day regimens

ORTHO-NOVUM® 7/7/7 Tablets

norethindrone/ethinyl estradiol

Low incidence of androgenic side effects

Each white tablet contains 0.5 mg norethindrone and 0.035 mg ethinyl estradiol. Each light peach tablet contains 0.75 mg norethindrone and 0.035 mg ethinyl estradiol. Each peach tablet contains 1 mg norethindrone and 0.035 mg ethinyl estradiol. Each green tablet in 28-day regimen contains inert ingredients.

MPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

NDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep vein thrombophlebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this brief summary is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this brief summary epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease, namely a *ratio* of the incidence of a disease among oral contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods. 1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS. a. Myocardial Infarction. An increased risk of myocardial infarction has been associated with oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers, especially in those 35 years of age and older among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in WARNINGS). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors. b. Thromboembolism. An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease associated with oral contraceptives is not related to length of use and disappears after pill use is stopped. A two- to four-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four weeks after delivery in women who elect not to breast feed. c. Cerebrovascular diseases. Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users, for both types of strokes, and smoking interacted to increase the risk of stroke. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for non-smokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women. d. Dose-related risk of vascular disease from oral contraceptives. A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the activity of the progestogen used in the contraceptive. The activity and amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing 0.035 mg or less of estrogen. e. Persistence of risk of vascular disease. There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral contraceptive formulations containing 50 micrograms or higher of estrogens. 2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE. One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. However, smokers 35 and older and non-smokers 40 and older who use oral contraceptives have a significant increase in mortality higher than those using other methods of birth control. These facts must be weighed in conjunction with failure rates for other methods and the risk associated with subsequent pregnancy. 3. CARCINOMA OF THE REPRODUCTIVE ORGANS. Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. While there are conflicting reports most studies suggest that use of oral contraceptives is not associated with an overall increase in the risk of developing breast cancer. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use. Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4. HEPATIC NEOPLASIA. Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia, papilledema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. The majority of recent studies also do not indicate a teratogenic effect, particularly in so far as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued until pregnancy is ruled out. 7. GALLBLADDER DISEASE. Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens. 8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS. Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. This effect has been shown to be directly related to estrogen dose. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects prediabetic and diabetic women in particular should be carefully monitored while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see WARNINGS 1a and 1d), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users. 9. ELEVATED BLOOD PRESSURE. An increase in blood pressure has been reported in women taking oral contraceptives, and this increase is more likely in older oral contraceptive users and with extended duration of use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing progestational activity. Women with a history of hypertension or hypertension-related diseases, or renal disease, should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension between former and never users. 10. HEADACHE. The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause. 11. BLEEDING IRREGULARITIES. Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent. 12. ECTOPIC PREGNANCY. Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. **PRECAUTIONS:** 1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine and liver function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3, increased norepinephrine-induced platelet aggregability. b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radio-immunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See WARNINGS section. 10. PREGNANCY. Pregnancy Category X. See CONTRAINDICATIONS and WARNINGS sections. 11. NURSING MOTHERS. Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child. **INFORMATION FOR THE PATIENT: See Patient Package Insert. ADVERSE REACTIONS:** An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see WARNINGS section). Thrombophlebitis and venous thrombosis with or without embolism. Arterial thromboembolism. Pulmonary embolism. Myocardial infarction. Cerebral hemorrhage. Cerebral thrombosis. Hypertension. Gallbladder disease. Hepatic adenomas or benign liver tumors. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea. Vomiting. Gastrointestinal symptoms (such as abdominal cramps and bloating). Breakthrough bleeding. Spotting. Change in menstrual flow. Amenorrhea. Temporary infertility after discontinuation of treatment. Edema. Melasma which may persist. Breast changes: tenderness, enlargement, secretion. Change in weight (increase or decrease). Change in cervical erosion and secretion. Diminution in lactation when given immediately postpartum. Cholestatic jaundice. Migraine. Rash (allergic). Mental depression. Reduced tolerance to carbohydrates. Vaginal candidiasis. Change in corneal curvature (steepening). Intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome. Cataracts. Changes in appetite. Cystitis-like syndrome. Headache. Nervousness. Dizziness. Hirsutism. Loss of scalp hair. Erythema multiforme. Erythema nodosum. Hemorrhagic eruption. Vaginitis. Porphyria. Impaired renal function. Hemolytic uremic syndrome. Acne. Changes in libido. Colitis. **OVERDOSAGE:** Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea and withdrawal bleeding may occur in females.

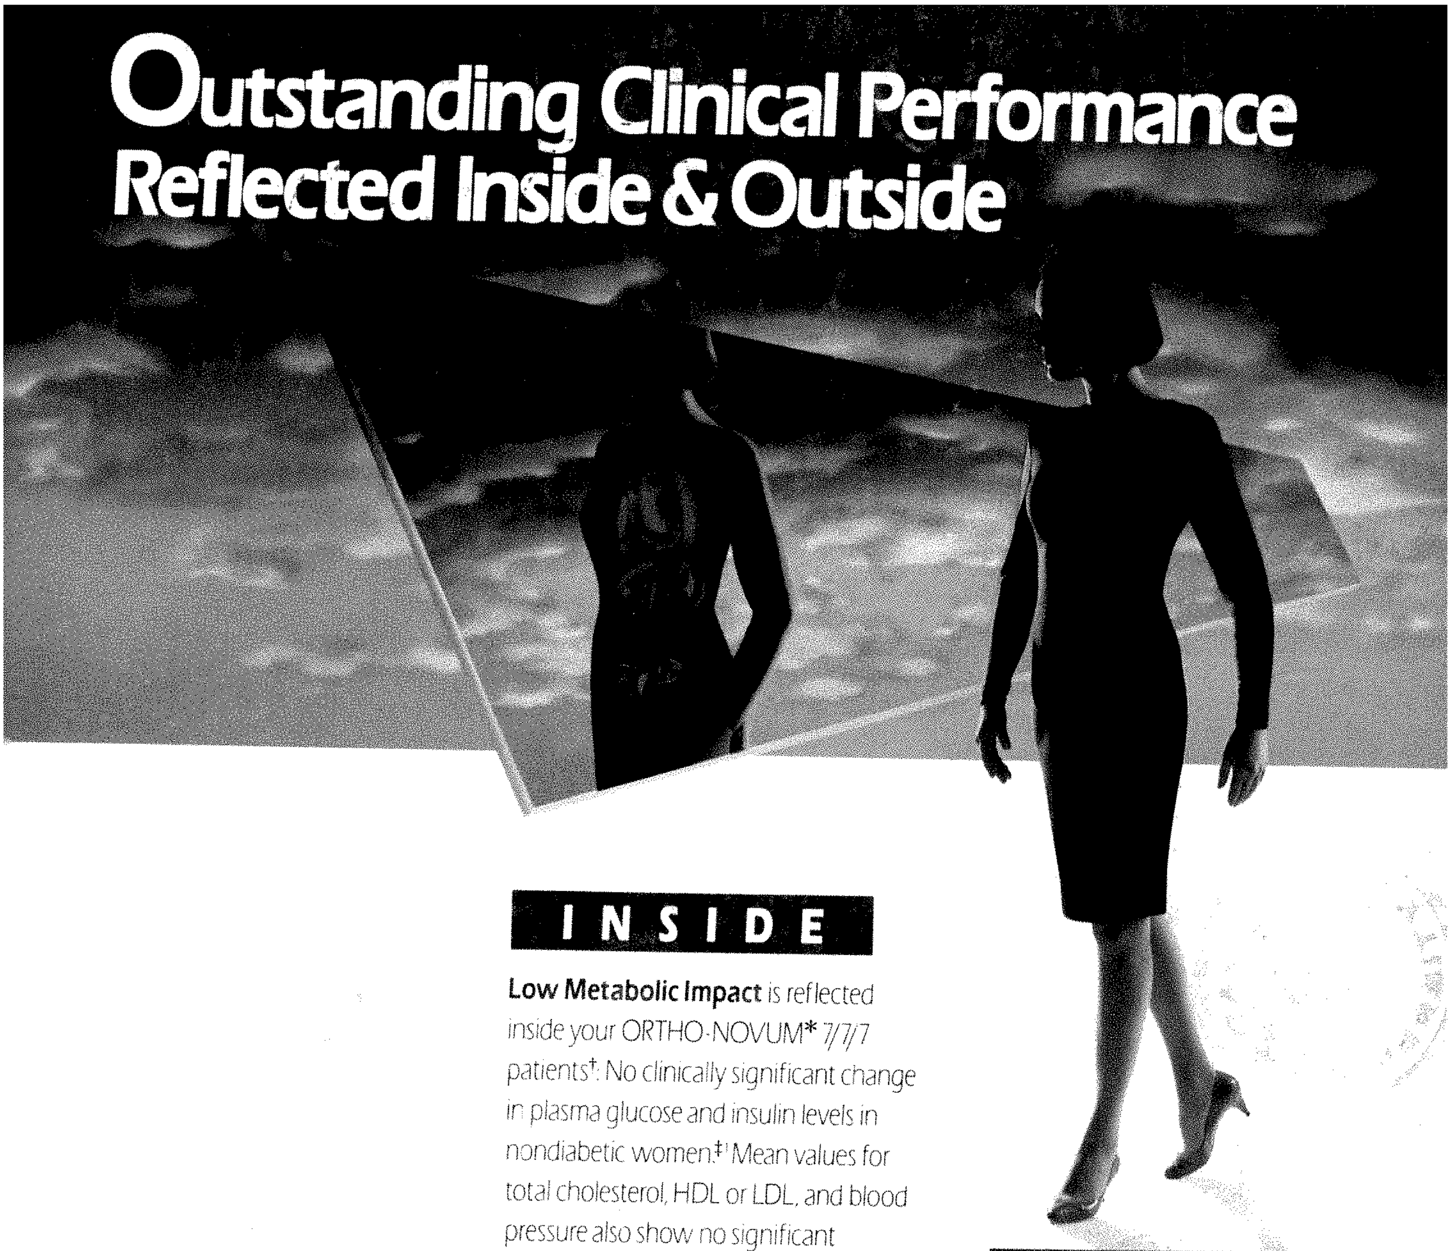
Outstanding Clinical Performance Reflected Inside & Outside



INSIDE

Low Metabolic Impact is reflected inside your ORTHO-NOVUM[*] 7/7/7 patients[†]: No clinically significant change in plasma glucose and insulin levels in nondiabetic women.[‡][1] Mean values for total cholesterol, HDL or LDL, and blood pressure also show no significant change.[§]

Excellent Cycle Control is another reflection of outstanding performance with ORTHO-NOVUM 7/7/7. You can expect low discontinuation rates due to breakthrough bleeding, spotting, and amenorrhea.

OUTSIDE

Low Incidence of Androgenic Side Effects—such as acne, oily skin, or hirsutism—is a visible reflection that your patients may notice; another is no clinically significant change in mean body weight. Inside and outside, the outstanding performance of ORTHO-NOVUM 7/7/7 is also an excellent reflection on you.

Low incidence of androgenic side effects

21- and 28-day regimens

ORTHO-NOVUM 7/7/7 Tablets

TRADEMARK

norethindrone/ethinyl estradiol

---

[*] Trademark

[†] Serious as well as minor side effects have been reported with the use of oral contraceptives. The physician should remain alert to the earliest manifestations of any symptoms of serious disease and discontinue oral contraceptive therapy when appropriate.

[‡] Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents.

[§] An increase in blood pressure has been reported in women taking oral contraceptives.

TRI-NORINYL®

Uniquely phased for all phases of a woman's reproductive life

ORAL CONTRACEPTIVE AGENTS: BRIEF SUMMARY

DESCRIPTION

TRI-NORINYL 21-DAY Tablets provide an oral contraceptive regimen of 7 blue tablets followed by 9 yellow-green tablets and 5 more blue tablets. Each blue tablet contains norethindrone 0.5 mg and ethinyl estradiol 0.035 mg and each yellow-green tablet contains norethindrone 1 mg and ethinyl estradiol 0.035 mg.

TRI-NORINYL 28-DAY Tablets provide a continuous oral contraceptive regimen of 7 blue tablets, 9 yellow-green tablets, 5 more blue tablets, and then 7 orange tablets. Each blue tablet contains norethindrone 0.5 mg and ethinyl estradiol 0.035 mg, each yellow-green tablet contains norethindrone 1 mg and ethinyl estradiol 0.035 mg, and each orange tablet contains inert ingredients.

INDICATIONS AND USAGE

Oral contraceptives are indicated for the prevention of pregnancy in women who elect to use these products as a method of contraception.

CONTRAINDICATIONS

Oral contraceptives should not be used in women who have the following conditions: Thrombophlebitis or thromboembolic disorders • A past history of deep vein thrombophlebitis or thromboembolic disorders • Cerebral vascular or coronary artery disease • Known or suspected carcinoma of the breast • Carcinoma of the endometrium, and known or suspected estrogen-dependent neoplasia • Undiagnosed abnormal genital bleeding • Cholestatic jaundice of pregnancy or jaundice with prior pill use • Hepatic adenomas, carcinomas or benign liver tumors • Known or suspected pregnancy

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia and gallbladder disease, although the risk of serious morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, hypercholesterolemia, obesity and diabetes.

Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks.

The information contained in this package insert is principally based on studies carried out in patients who used oral contraceptives with formulations containing 0.05 mg or higher of estrogen. The effects of long-term use with lower dose formulations of both estrogens and progestogens remain to be determined.

Throughout this labeling, epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease. Relative risk, the *ratio* of the incidence of a disease among oral contraceptive users to that among non-users, cannot be assessed directly from case control studies, but the odds ratio obtained is a measure of relative risk. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide not only a measure of the relative risk but a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and non-users. The attributable risk does provide information about the actual occurrence of a disease in the population.

1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS

a. Myocardial Infarction

An increased risk of myocardial infarction has been attributed to oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be 2 to 6. The risk is very low under the age of 30. However, there is the possibility of a risk of cardiovascular disease even in very young women who take oral contraceptives.

Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women 35 or older, with smoking accounting for the majority of excess cases.

Mortality rates associated with circulatory disease have been shown to increase substantially in smokers over the age of 35 and non-smokers over the age of 40 among women who use oral contraceptives.

Oral contraceptives may compound the effects of well-known risk factors for coronary artery disease, such as hypertension, diabetes, hyperlipidemias, hypercholesterolemia, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and impair oral glucose tolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see **WARNINGS**, section 9). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors.

b. Thromboembolism

An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. One cohort study has shown the relative risk to be somewhat lower, about 3 for new cases (subjects with no past history of venous thrombosis or varicose veins) and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease due to oral contraceptives is not related to length of use and disappears after pill use is stopped.

A 2- to 6-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. If feasible, oral contraceptives should be discontinued at least 4 weeks prior to and for 2 weeks after elective surgery and during and following prolonged immobilization. Since the immediate postpartum period also is associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than 4 to 6 weeks after delivery in women who elect not to breast feed.

c. Cerebrovascular diseases

An increase in both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes) has been shown in users of oral contraceptives. In general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users for both types of strokes while smoking interacted to increase the risk for hemorrhagic strokes.

In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for non-smokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk also is greater in women 35 or older and among smokers.

d. Dose-related risk of vascular disease from oral contraceptives

A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with some progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the nature and absolute amount of progestogens used in the contraceptives. The amount of both hormones should be considered in the choice of an oral contraceptive.

Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing the lowest estrogen content that produces satisfactory results for the individual.

e. Persistence of risk of vascular disease

There are three studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for 5 or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. Subarachnoid hemorrhage also has a significantly increased relative risk after termination of use of oral contraceptives. However, these studies were performed with oral contraceptive formulations containing 0.05 mg or higher of estrogen.

2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE

One study gathered data from a variety of sources which have estimated the mortality rates associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. The observation of a possible increase in risk of mortality with age for oral contraceptive users is based on data gathered in the 1970's—but not reported in the U.S. until 1983. However, current clinical practice involves the use of lower estrogen dose formulations combined with careful restriction of oral contraceptive use to women who do not have the various risk factors listed in this labeling.

Because of these changes in practice and, also, because of some limited new data which suggest that the risk of cardiovascular disease with the use of oral contraceptives may now be less than previously observed, the Fertility and Maternal Health Drugs Advisory Committee was asked to review the topic in 1989. The Committee concluded that although cardiovascular disease risks may be increased with oral contraceptive use after age 40 in healthy non-smoking women (even with the newer low-dose formulations), there are greater potential health risks associated with pregnancy in older women and with the alternative surgical and medical procedures which may be necessary if such women do not have access to effective and acceptable means of contraception.

Therefore, the Committee recommended that the benefits of oral contraceptive use by healthy non-smoking women over 40 may outweigh the possible risks. Of course, older women, as all women who take oral contraceptives, should take the lowest possible dose formulation that is effective.

3. CARCINOMA OF THE BREAST AND REPRODUCTIVE ORGANS

Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. The evidence in the literature suggests that use of oral contraceptives is not associated with an increase in the risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone study also showed no latent effect on the risk of breast cancer for at least a decade following long-term use. A few studies have shown a slightly increased relative risk of developing breast cancer, although the methodology of these studies, which included differences in examination of users and non-users and differences in age at start of use, has been questioned. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use.

Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors.

In spite of many studies of the relationship between oral contraceptive use and breast or cervical cancers, a cause and effect relationship has not been established.

4. HEPATIC NEOPLASIA

Benign hepatic adenomas are associated with oral contraceptive use although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases per 100,000 for users, a risk that increases after 4 or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through intra-abdominal hemorrhage.

Studies in the United States and Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (> 8 years) oral contraceptive users. However, these cancers are extremely rare in the United States and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users is less than 1 per 1,000,000 users.

5. OCULAR LESIONS

There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately.

6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY

Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. More recent studies do not suggest a teratogenic effect, particularly insofar as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy.

The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion.

It is recommended that for any patient who has missed 2 consecutive periods, pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued if pregnancy is confirmed.

7. GALLBLADDER DISEASE

Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens.

8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS

Oral contraceptives have been shown to impair oral glucose tolerance. Oral contraceptives containing greater than 0.075 mg of estrogen cause glucose intolerance with impaired insulin secretion, while lower doses of estrogen may produce less glucose intolerance. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects, prediabetic and diabetic women should be carefully observed while taking oral contraceptives.

Some women may develop persistent hypertriglyceridemia while on the pill. As discussed earlier (see **WARNINGS**, sections 1a. and 1d.), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users.

9. ELEVATED BLOOD PRESSURE

An increase in blood pressure has been reported in women taking oral contraceptives. The incidence of risk also was reported to increase with continued use and among older women. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing concentrations of progestogens.

Women with a history of hypertension or hypertension-related diseases or renal disease should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives and there is no difference in the occurrence of hypertension among ever- and never-users.

10. HEADACHE

The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause.

11. BLEEDING IRREGULARITIES

Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first 3 months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding, as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out.

Some women may encounter post-pill amenorrhea or oligomenorrhea, especiall when such a condition was pre-existent.

PRECAUTIONS

1. PHYSICAL EXAMINATION AND FOLLOW-UP

A complete medical history and physical examination should be taken prior to the ini ation or reinstitution of oral contraceptives and at least annually during use of oral co traceptives. These physical examinations should include special reference to bloo pressure, breasts, abdomen and pelvic organs, including cervical cytology and rel vant laboratory tests. In case of undiagnosed, persistent or recurrent abnormal vagina bleeding, appropriate diagnostic measures should be conducted to rule out mali nancy. Women with a strong family history of breast cancer or who have breast nodule should be monitored with particular care.

2. LIPID DISORDERS

Women who are being treated for hyperlipidemias should be followed closely if the elect to use oral contraceptives. Some progestogens may elevate LDL levels and ma render the control of hyperlipidemias more difficult.

3. LIVER FUNCTION

If jaundice develops in any woman receiving oral contraceptives the medication shoul be discontinued. Steroid hormones may be poorly metabolized in patients wit impaired liver function.

4. FLUID RETENTION

Oral contraceptives may cause some degree of fluid retention. They should be pre scribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention.

5. EMOTIONAL DISORDERS

Women with a history of depression should be carefully observed and the drug discon tinued if depression recurs to a serious degree.

6. CONTACT LENSES

Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist.

7. DRUG INTERACTIONS

Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar associ ation though less marked, has been suggested with barbiturates phenylbutazone phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines.

8. INTERACTIONS WITH LABORATORY TESTS

Certain endocrine and liver function tests and blood components may be affected by oral contraceptives:

a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.

b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radioimmunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG. Free T4 concentration is unaltered.

c. Other binding proteins may be elevated in serum.

d. Sex steroid binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged.

e. Triglycerides may be increased.

f. Glucose tolerance may be decreased.

g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives.

9. CARCINOGENESIS

See **WARNINGS** section.

10. PREGNANCY

Pregnancy Category X. See **CONTRAINDICATIONS** and **WARNINGS** sections.

11. NURSING MOTHERS

Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child.

INFORMATION FOR THE PATIENT

See **PATIENT LABELING.**

ADVERSE REACTIONS

An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see **WARNINGS** section): Thrombophlebitis • Arterial thromboembolism • Pulmonary embolism • Myocardial infarction • Cerebral hemorrhage • Cerebral thrombosis • Hypertension • Gallbladder disease • Hepatic adenomas, carcinomas or benign liver tumors

There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: Mesenteric thrombosis • Retinal thrombosis

The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea • Vomiting • Gastrointestinal symptoms (such as abdominal cramps and bloating) • Breakthrough bleeding • Spotting • Change in menstrual flow • Amenorrhea • Temporary infertility after discontinuation of treatment • Edema • Melasma which may persist • Breast changes: tenderness, enlargement, secretion • Change in weight (increase or decrease) • Change in cervical erosion and secretion • Diminution in lactation when given immediately postpartum • Cholestatic jaundice • Migraine • Rash (allergic) • Mental depression • Reduced tolerance to carbohydrates • Vaginal candidiasis • Change in corneal curvature (steepening) • Intolerance to contact lenses

The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome • Cataracts • Changes in appetite • Cystitis-like syndrome • Headache • Nervousness • Dizziness • Hirsutism • Loss of scalp hair • Erythema multiforme • Erythema nodosum • Hemorrhagic eruption • Vaginitis • Porphyria • Impaired renal function • Hemolytic uremic syndrome • Budd-Chiari syndrome • Acne • Changes in libido • Colitis

OVERDOSAGE

Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

NON-CONTRACEPTIVE HEALTH BENEFITS

The following non-contraceptive health benefits related to the use of oral contraceptives are supported by epidemiological studies which largely utilized oral contraceptive formulations containing estrogen doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol.

Effects on menses: • Increased menstrual cycle regularity • Decreased blood loss and decreased incidence of iron deficiency anemia • Decreased incidence of dysmenorrhea

Effects related to inhibition of ovulation: • Decreased incidence of functional ovarian cysts • Decreased incidence of ectopic pregnancies

Effects from long-term use: • Decreased incidence of fibroadenomas and fibrocystic disease of the breast • Decreased incidence of acute pelvic inflammatory disease • Decreased incidence of endometrial cancer • Decreased incidence of ovarian cancer

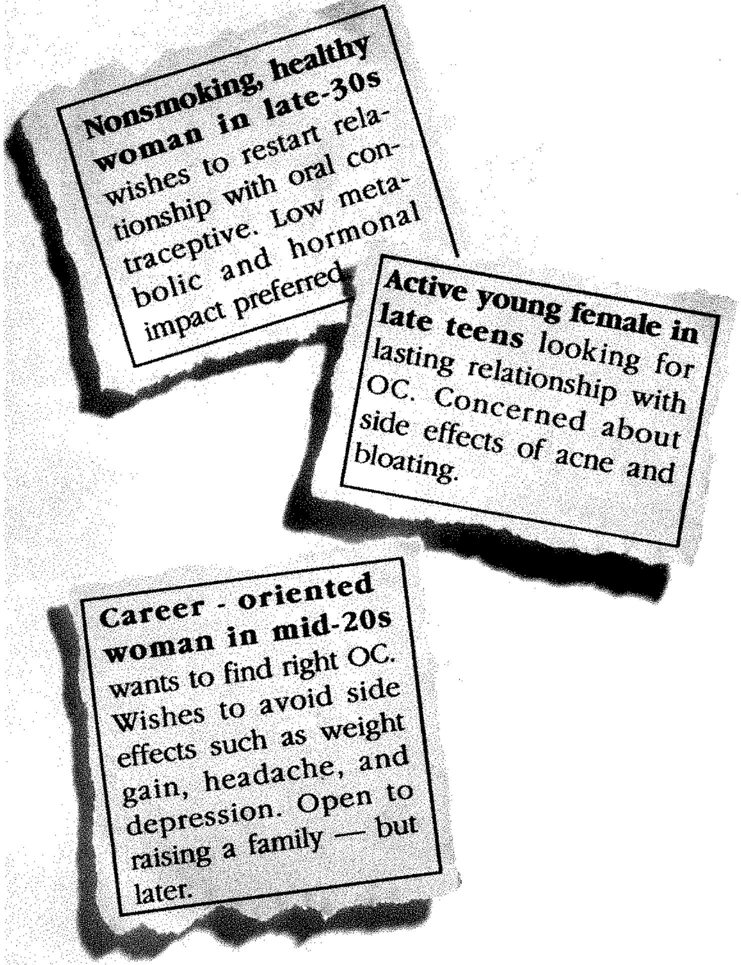
Rev. May 1990

SYNTEX

SYNTEX LABORATORIES, INC.
PALO ALTO, CA 94304



Nonsmoking, healthy woman in late-30s wishes to restart relationship with oral contraceptive. Low metabolic and hormonal impact preferred.

Active young female in late teens looking for lasting relationship with OC. Concerned about side effects of acne and bloating.

Career - oriented woman in mid-20s wants to find right OC. Wishes to avoid side effects such as weight gain, headache, and depression. Open to raising a family — but later.

A personalized approach to oral contraceptives.

Because Tri-Norinyl is uniquely phased for all phases of a woman's reproductive life, it's ideal for a wide range of patient types:

Older, nonsmoking patients restarting contraception: The only multiphasic with norethindrone that *lowers* progestin in late cycle to minimize overall hormonal and metabolic impact.

Career-oriented patients delaying childbearing: Reduced progestin helps minimize side effects such as weight gain, headache, and depression.

Younger patients just starting contraception: Low-impact progestin lowers risk of acne and bloating; mid-cycle increase enhances support when breakthrough bleeding is most likely to occur.

(NORETHINDRONE AND ETHINYL ESTRADIOL) TABLETS

TRI-NORINYL®

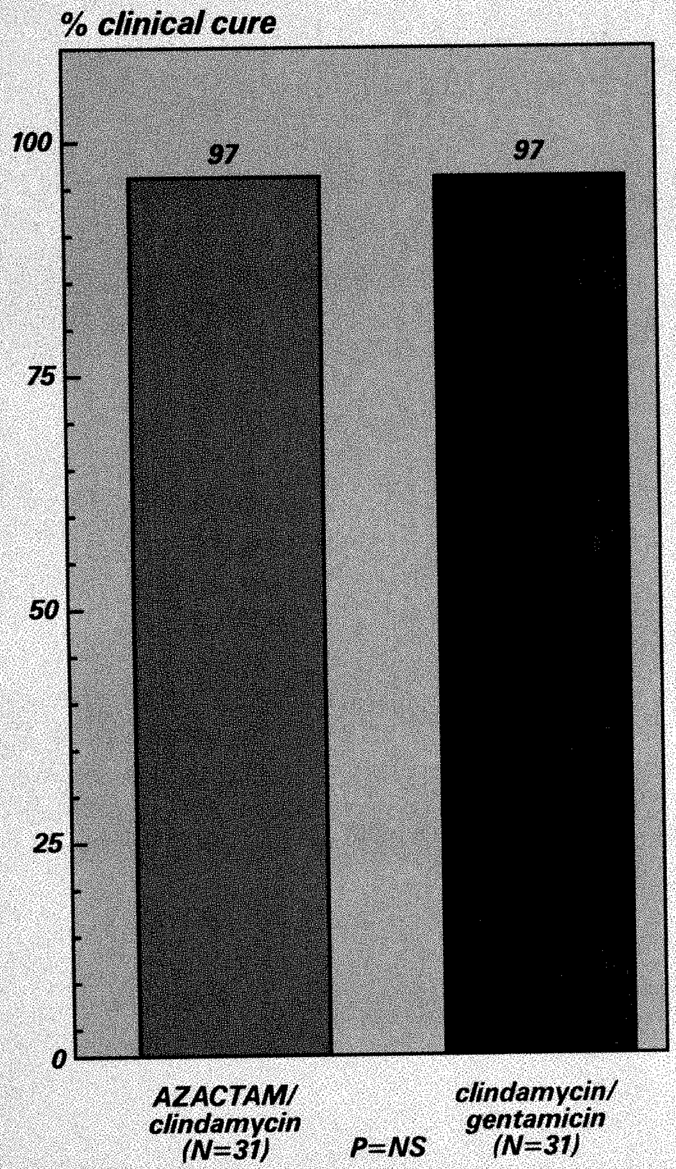
Uniquely phased for all phases of a woman's reproductive life

Committed to the OB/GYN and women's healthcare

SYNTEX
SYNTEX LABORATORIES, INC.
PALO ALTO, CA 94304

Serious as well as minor side effects have been reported following the use of all oral contraceptives. These include thromboembolic disease. Please see next page for brief summary of prescribing information. © 1990 Syntex Laboratories, Inc. 814-H2-201-90

IN POSTPARTUM ENDOMETRITIS*



A randomized, comparative trial of AZACTAM versus gentamicin, each with clindamycin, for the treatment of endometritis after delivery.[1]

No universal criteria exist that may satisfy a single definition of "cure." Use of this term may vary between clinical settings and investigators, and the reader is urged to consult the reference listed.

*Due to susceptible organisms.

†Although a useful guide, in vitro data do not necessarily correlate with therapeutic outcome.

‡Antibiotics should be given with caution to any patient who has had some forr of allergy, particularly to drugs. See full prescribing information for recommer dations on patients with immediate hypersensitivity reactions to penicillins.

Following IV administration, the most commonly seen adverse reactions oc curred in less than 2% of patients, including local reactions, diarrhea, nause vomiting, and rash.

more than you're expecting...

- *Broad aerobic gram-negative in vitro coverage, including Escherichia coli, Proteus mirabilis, and Enterobacter cloacae.*[†]
- *Greater than 90% cure rates in combination with clindamycin.*[1-3]
- *No time-consuming, costly, routine therapeutic drug monitoring.*
- *May be admixed in the same bag with clindamycin.*
- *May be used in penicillin-allergic patients.*[‡]
- *Pregnancy Category B.*

There are no adequate and well-controlled studies in pregnant women. AZACTAM should be used in pregnant women only if clearly needed.

Azactam®

aztreonam

A logical alternative to aminoglycosides.

Please see adjacent page for brief summary of prescribing information.

Azactam®

aztreonam

AZACTAM* FOR INJECTION
Aztreonam For Injection

DESCRIPTION–AZACTAM (aztreonam, Squibb) is the first member of a new class of antibiotics classified as monobactams. AZACTAM is a totally synthetic bactericidal antibiotic with activity against a wide spectrum of gram-negative aerobic pathogens. The monobactams, having a unique monocyclic beta-lactam nucleus, are structurally different from other beta-lactam antibiotics.

AZACTAM For Injection is a sterile, nonpyrogenic, sodium-free, white to yellowish-white lyophilized cake, containing approximately 780 mg arginine per gram of aztreonam for intramuscular or intravenous use following constitution. Aqueous solutions of the product have a pH in the range of 4.5-7.5.

INDICATIONS AND USAGE–Before initiating treatment with AZACTAM, appropriate specimens should be obtained for isolation of the causative organism(s) and for determination of susceptibility to aztreonam. Treatment with AZACTAM may be started empirically before results of the susceptibility testing are available; subsequently, appropriate antibiotic therapy should be continued.

AZACTAM For Injection is indicated for the treatment of the following infections caused by susceptible gram-negative microorganisms: **Urinary Tract Infections** (complicated and uncomplicated), including pyelonephritis and cystitis (initial and recurrent) caused by *Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa, Enterobacter cloacae, Klebsiella oxytoca*, Citrobacter* species* and *Serratia marcescens**. **Lower Respiratory Tract Infections,** including pneumonia and bronchitis caused by *Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Haemophilus influenzae, Proteus mirabilis, Enterobacter* species and *Serratia marcescens**. **Septicemia** caused by *Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Proteus mirabilis*, Serratia marcescens** and *Enterobacter* species. **Skin and Skin-Structure Infections,** including those associated with postoperative wounds, ulcers and burns caused by *Escherichia coli, Proteus mirabilis, Serratia marcescens, Enterobacter* species, *Pseudomonas aeruginosa, Klebsiella pneumoniae,* and *Citrobacter* species*. **Intra-abdominal Infections,** including peritonitis caused by *Escherichia coli, Klebsiella* species, including *K. pneumoniae, Enterobacter* species including *E. cloacae*, Pseudomonas aeruginosa, Citrobacter* species* including *C. freundii** and *Serratia* species* including *S. marcescens**. **Gynecologic Infections,** including endometritis and pelvic cellulitis caused by *Escherichia coli, Klebsiella pneumoniae*, Enterobacter* species* including *E. cloacae**, and *Proteus mirabilis**.

AZACTAM is indicated for adjunctive therapy to surgery in the management of infections caused by susceptible organisms, including abscesses, infections complicating hollow viscus perforations, cutaneous infections and infections of serous surfaces. AZACTAM is effective against most of the commonly encountered gram-negative aerobic pathogens seen in general surgery.

Concurrent Therapy–Concurrent initial therapy with other antimicrobial agents and AZACTAM is recommended before the causative organisms(s) is known in seriously ill patients who are also at risk of having an infection due to gram-positive aerobic pathogens. If anaerobic organisms are also suspected, therapy should be initiated using an antianaerobic agent concurrently with AZACTAM. Certain antibiotics (e.g., cefoxitin, imipenem) may induce high levels of beta-lactamase *in vitro* in some gram-negative aerobes such as *Enterobacter* and *Pseudomonas* species, resulting in antagonism to many beta-lactam antibiotics including aztreonam. These *in vitro* findings suggest that such beta-lactamase inducing antibiotics not be used concurrently with aztreonam. Following identification and susceptibility testing, appropriate antibiotic therapy should be continued.

CONTRAINDICATIONS–Aztreonam is contraindicated in patients with known allergy to this antibiotic.

WARNINGS–Pseudomembranous colitis has been reported with nearly all antibacterial agents, including aztreonam, and may range in severity from mild to life-threatening. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is one primary cause of "antibiotic-associated colitis."

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to drug discontinuation alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an oral antibacterial drug effective against *C. difficile* (e.g., vancomycin). Careful inquiry should be made for a history of hypersensitivity reaction to any antibiotic or other drugs. Antibiotics should be given with caution to any patient who has had some form of allergy, particularly to drugs. It is recommended that patients who have had immediate hypersensitivity reactions (e.g., anaphylacti or urticarial) to penicillins and/or cephalosporins should be followed with special care If an allergic reaction to aztreonam occurs, discontinue the drug and institute supportive treatment as appropriate (e.g., maintenance of ventilation, pressor amines antihistamines, corticosteroids). Serious hypersensitivity reactions may require epinephrine and other emergency measures.

PRECAUTIONS–General: In patients with impaired hepatic or renal function, appropriate monitoring is recommended during therapy. If an aminoglycoside is used concurrently with aztreonam, especially if high dosages of the former are used or i therapy is prolonged, renal function should be monitored because of the potentia nephrotoxicity and ototoxicity of aminoglycoside antibiotics. The use of antibiotics may promote the overgrowth of nonsusceptible organisms, including gram-positive organisms and fungi. Should superinfection occur during therapy, appropriate measures should be taken.

Carcinogenesis, Mutagenesis, Impairment of Fertility–Carcinogenicity studies in animals have not been performed. Genetic toxicology studies performed *in vivo* and *in vitro* with aztreonam in several standard laboratory models revealed no evidence of mutagenic potential at the chromosomal or gene level. Two-generation reproduction studies in rats at daily doses up to 20 times the maximum recommended human dose prior to and during gestation and lactation, revealed no evidence of impaired fertility. There was a slightly reduced survival rate during the lactation period in the offspring of rats that received the highest dosage, but not in offspring of rats that received five times the maximum recommended human dose.

Pregnancy–Pregnancy Category B: Aztreonam crosses the placenta and enters the fetal circulation. Studies in pregnant rats and rabbits, with daily doses up to 15 and 5 times, respectively, the maximum recommended human dose, revealed no evidence of embryo- or fetotoxicity or teratogenicity. No drug induced changes were seen in any of the maternal, fetal or neonatal parameters that were monitored in rats receiving 15 times the maximum recommended human dose of aztreonam during late gestation and lactation. There are no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, aztreonam should be used during pregnancy only if clearly needed.

Nursing Mothers–Aztreonam is excreted in breast milk in concentrations that are less than 1% of concentrations determined in simultaneously obtained maternal serum; consideration should be given to temporary discontinuation of nursing and use of formula feedings.

Pediatric Use–Safety and effectiveness have not been established in infants and children.

ADVERSE REACTIONS–Local reactions such as phlebitis/thrombophlebitis following IV administration, and discomfort/swelling at the injection site following IM administration occurred at rates of approximately 1.9% and 2.4%, respectively. Systemic reactions (considered to be related to therapy or of uncertain etiology) occurring at an incidence of 1 to 1.3% include diarrhea, nausea and/or vomiting, and rash. Reactions occurring at an incidence of less than 1% are listed within each body system in order of decreasing severity; *Hypersensitivity*–anaphylaxis. *Hematologic*–pancytopenia, neutropenia, thrombocytopenia, anemia, leukocytosis, thrombocytosis. *Gastrointestinal*–abdominal cramps; rare cases of *C. difficile*-associated diarrhea, including pseudomembranous colitis, or gastrointestinal bleeding have been reported. Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment (see WARNINGS). *Dermatologic*–purpura, erythema multiforme, urticaria, exfoliative dermatitis, petechiae, pruritus, diaphoresis. *Cardiovascular*–hypotension, transient ECG changes (ventricular bigeminy and PVC). *Respiratory*–one patient experienced flushing, chest pain, and dyspnea. *Hepatobiliary*–hepatitis, jaundice. *Nervous System*–seizure, confusion, vertigo, paresthesia, insomnia, dizziness. *Musculoskeletal*–muscular aches. *Special Senses*–tinnitus, diplopia, mouth ulcer, altered taste, numb tongue, sneezing and nasal congestion, halitosis. *Other*–vaginal candidiasis, vaginitis, breast tenderness. *Body as a Whole*–weakness, headache, fever, malaise.

Adverse Laboratory Changes–Those reported without regard to drug relationship during clinical trials were: *Hepatic*–elevations of AST (SGOT), ALT (SGPT), and alkaline phosphatase; signs or symptoms of hepatobiliary dysfunction occurred in less than 1% of recipients (see above). *Hemic*–increases in prothrombin and partial thromboplastin times, eosinophilia, positive Coombs test. *Renal*–increases in serum creatinine.

OVERDOSAGE–If necessary, aztreonam may be cleared from the serum by hemodialysis and/or peritoneal dialysis.

DOSAGE AND ADMINISTRATION–Dosage adjustments are recommended for patients with impaired renal function. In elderly patients, estimates of creatinine clearance should be obtained and appropriate dosage modifications made if necessary.

HOW SUPPLIED–AZACTAM For Injection (Aztreonam For Injection)–Lyophilized–is supplied in single-dose 15 mL vials containing **500 mg,** or **1 g**/vial; in single-dose 30 mL vials containing **2 g**/vial; and in single-dose 100 mL intravenous infusion bottles containing **500 mg** or **1 g** or **2 g**/bottle.

Consult package insert before prescribing AZACTAM (aztreonam). (J4-231C)

CEFOTAN® IM/IV
(cefotetan disodium)

In intra-abdominal and gynecologic infection due to indicated organisms

For Intravenous or Intramuscular Use
BRIEF SUMMARY

INDICATIONS AND USAGE

TREATMENT: CEFOTAN® (cefotetan disodium) is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary tract infections caused by *E coli, Klebsiella* species (including *K pneumoniae*), *Proteus mirabilis* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris, Providencia rettgeri,* and *Morganella morganii*).

Lower respiratory tract infections caused by *Streptococcus pneumoniae* (formerly *D pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K pneumoniae*), and *E coli.*

Skin and skin structure infections caused by *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus pyogenes* and *Streptococcus* species (excluding enterococci), and *E coli.*

Gynecologic infections caused by *Staphylococcus aureus** (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus* species (excluding enterococci), *E coli, Proteus mirabilis, Neisseria gonorrhoeae, Bacteroides* species (excluding *B distasonis, B ovatus, B thetaiotaomicron*), *Fusobacterium* species,* and gram-positive anaerobic cocci (including *Peptococcus* and *Peptostreptococcus* species*).

Intra-abdominal infections caused by *E coli, Klebsiella* species (including *K pneumoniae**), *Streptococcus* species (excluding enterococci), and *Bacteroides* species (excluding *B distasonis, B ovatus, B thetaiotaomicron*).

Bone and joint infections caused by *Staphylococcus aureus.**

*Efficacy for this organism in this organ system was studied in fewer than ten infections.

Specimens for bacteriological examination should be obtained in order to isolate and identify causative organisms and to determine their susceptibilities to cefotetan. Therapy may be instituted before results of susceptibility studies are known; however, once these results become available, the antibiotic treatment should be adjusted accordingly.

In cases of confirmed or suspected gram-positive or gram-negative sepsis or in patients with other serious infections in which the causative organism has not been identified, it is possible to use CEFOTAN concomitantly with an aminoglycoside. Cefotetan combinations with aminoglycosides have been shown to be synergistic in vitro against many Enterobacteriaceae and also some other gram-negative bacteria. The dosage recommended in the labeling of both antibiotics may be given and depends on the severity of the infection and the patient's condition.

NOTE: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycosidic antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

PROPHYLAXIS: The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (eg, cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

Before therapy with CEFOTAN is instituted, careful inquiry should be made to determine whether the patient has had previous hypersensitivity reactions to cefotetan disodium, cephalosporins, penicillins, or other drugs. This product should be given cautiously to penicillin-sensitive patients. Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs. If an allergic reaction to CEFOTAN occurs, discontinue the drug. Serious acute hypersensitivity reactions may require epinephrine and other emergency measures.

Pseudomembranous colitis has been reported with the use of cephalosporins (and other broad-spectrum antibiotics); therefore, it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use.

Treatment with broad-spectrum antibiotics may alter normal flora of the colon and may permit overgrowth of clostridia. Studies indicate a toxin produced by *Clostridium difficile* is one primary cause of antibiotic-associated colitis. Cholestyramine and colestipol resins have been shown to bind the toxin in vitro.

Mild cases of colitis may respond to drug discontinuance alone. Moderate to severe cases should be managed with fluid, electrolyte, and protein supplementation as indicated. When the colitis is not relieved by drug discontinuance, or when it is severe, oral vancomycin is the treatment of choice for antibiotic-associated pseudomembranous colitis produced by *C difficile.* Other causes should also be considered.

PRECAUTIONS

GENERAL: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity. Those at risk include patients with renal or hepatic impairment or poor nutritional state, the elderly and patients with cancer. Prothrombin times should be monitored in patients at risk and exogenous vitamin K administered as indicated.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

INFORMATION FOR PATIENTS: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc.) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

DRUG INTERACTIONS: Although to date nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

DRUG/LABORATORY TEST INTERACTIONS: A false positive reaction for glucose in urine may occur with Benedict's or Fehling's solution.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels by Jaffe reaction and produce false increases in the levels of creatinine reported.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approximately 8-16 times the usual adult human dose) on days 6-35 of life (thought to be

CEFOTAN® (cefotetan disodium)

developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approximately 2-4 times the usual human dose) only 1 of 10 treated animals was affected, and the degree of degeneration was mild.

Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

USAGE IN PREGNANCY: Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

USAGE IN NURSING MOTHERS: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies, the following adverse effects were considered related to CEFOTAN therapy.

Gastrointestinal symptoms occurred in 1.5% of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700).

Hematologic laboratory abnormalities occurred in 1.4% of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300).

Hepatic enzyme elevations occurred in 1.2% of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2% of patients and included rash (1 in 150) and itching (1 in 700).

Local effects were reported in less than 1.0% of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500). During postmarketing experience with CEFOTAN, anaphylactic reactions and transient thrombocytopenia have been reported.

DOSAGE AND ADMINISTRATION

TREATMENT: The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6* grams	3 g every 12 hours IV

*Maximum daily dosage should not exceed 6 grams.

PROPHYLAXIS: To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION: When renal function is impaired, a reduced dosage schedule must be employed. The following dosage guidelines may be used.

DOSAGE GUIDELINES FOR PATIENTS WITH IMPAIRED RENAL FUNCTION

Creatinine Clearance mL/min	Dose	Frequency
>30	Usual Recommended Dosage*	Every 12 hours
10-30	Usual Recommended Dosage*	Every 24 hours
<10	Usual Recommended Dosage*	Every 48 hours

*Dose determined by the type and severity of infection, and susceptibility of the causative organism.

Alternatively, the dosing interval may remain constant at 12 hour intervals, but the dose reduced to one-half the usual recommended dose for patients with a creatinine clearance of 10-30 mL/min, and one-quarter the usual recommended dose for patients with a creatinine clearance of less than 10 mL/min.

When only serum creatinine levels are available, creatinine clearance may be calculated from the following formula. The serum creatinine level should represent a steady state of renal function.

$$\text{Males:} \quad \frac{\text{Weight (kg)} \times (140 - \text{age})}{72 \times \text{serum creatinine (mg/100 mL)}}$$

$$\text{Females:} \quad 0.9 \times \text{value for males}$$

Cefotetan is dialyzable and it is recommended that for patients undergoing intermittent hemodialysis, one-quarter of the usual recommended dose be given every 24 hours on days between dialysis and one-half the usual recommended dose on the day of dialysis.

HOW SUPPLIED

CEFOTAN is a dry, white to pale yellow powder supplied in vials containing cefotetan disodium equivalent to 1 g and 2 g cefotetan activity for intravenous and intramuscular administration. The 1 g dose is available in 10 mL and 100 mL vials, and the 2 g dose is available in 20 mL and 100 mL vials. CEFOTAN is also available in a pharmacy bulk package of 10 g in 100 mL vials. The vials should not be stored at temperatures above 22°C and should be protected from light.

1 g in 10 mL vial (NDC 0038-0376-10); 2 g in 20 mL vial (NDC 0038-0377-20); 1 g in 100 mL vial (NDC 0038-0376-11); 2 g in 100 mL vial (NDC 0038-0377-21); 10 g in 100 mL vial (NDC 0038-0375-10).

Cigarette smoking during pregnancy in relation to placenta previa 28

Michelle A. Williams, SM, Robert Mittendorf, MD, MPH, Ellice Lieberman, MD, DrPH,
Richard R. Monson, MD, ScD, Stephen C. Schoenbaum, MD, MPH, and David R. Genest, MD
Boston, Massachusetts

When compared with nonsmokers, women who smoked cigarettes during pregnancy had a 2.6-fold increase in risk for placenta previa.

Medication in early pregnancy: Prevalence of use and relationship to maternal characteristics 33

Simone Buitendijk, MD, MPH, and Michael B. Bracken, PhD, MPH
New Haven, Connecticut

Analysis of the prevalence and characteristics of medication use in pregnancy suggests a relationship of use with other risk-taking behaviors.

Extensive pulmonary embolism presenting as severe adult respiratory distress syndrome after surgical resection of a cornual pregnancy 41

Derek J. tenHoopen, MD, David M. Sherer, MD, Jacques S. Abramowicz, MD, and
Peter J. Papadakos, MD
Rochester, New York

Extensive pulmonary embolism presenting as adult respiratory distress syndrome associated with a Po_2 of 9 mm Hg after surgical resection of a cornual pregnancy with survival is presented.

Ten years after cryosurgical treatment of cervical intraepithelial neoplasia 43

John Dræby-Kristiansen, MD, Michael Garsaae, MD, Morten Bruun, MD, and Kristen Hansen, MD
Herning, Denmark

Follow-up of 96 patients for at least 10 years after cryosurgery for grade 2 or 3 cervical intraepithelial neoplasia showed 92% effectiveness of treatment.

Recurrence of ectopic pregnancy: The role of salpingitis 46

M. Riduan Joesoef, MD, PhD, L. Westrom, MD, G. Reynolds, PhD, P. Marchbanks, PhD, and
W. Cates, MD, MPH
Atlanta, Georgia, and Lund, Sweden

Salpingitis is a risk factor for first ectopic pregnancy, but once a woman has an ectopic pregnancy, previous salpingitis may not add any incremental risk.

The prevalence of autoantibodies during third-trimester pregnancy complicated by hypertension or idiopathic fetal growth retardation 51

J. Milliez, MD, F. Lelong, MD, N. Bayani, MD, D. Jannet, MD, M. El Medjadji, MD, H. Latrous, MD,
M. Hammami, MD, and B.J. Paniel, MD
Creteil, France

In third-trimester pregnancy the prevalence of antiphospholipids and autoantibodies was higher in those with hypertension (16%) than in those with idiopathic fetal growth retardation (2%) or normal pregnancy (3%) ($p < 0.01$).

Automated analysis of near-term antepartum fetal heart rate in relation to fetal behavioral states: The Sonicaid System 8000 57

Rob Mantel, MD, Herman P. van Geijn, MD, Inge A.P. Ververs, MD, and Frans J.A. Copray, MD
Amsterdam, The Netherlands

Automated analysis of near-term antepartum fetal heart rate shows that comprehension of the fetal behavioral state concept is essential to distinguish physiologic quiet sleep from fetal compromise.

A life-threatening sexually transmitted *Haemophilus influenzae* in septic abortion: A case report 66

Orit Pinhas-Hamiel, MD, Eyal Schiff, MD, Gilad Ben-Baruch, MD, Shlomo Mashiach, MD, and Brian Reichman, MB, ChB
Tel-Hashomer, Israel

An uncommon case of sexually transmitted *Haemophilus influenzae* life-threatening bacteremia associated with a septic abortion is presented.

The association between human papillomavirus deoxyribonucleic acid status and the results of cytologic rescreening tests in young, sexually active women 67

Anna-Barbara Moscicki, MD, Joel M. Palefsky, MD, John Gonzales, MD, and Gary K. Schoolnik, MD
San Francisco and Stanford, California

A significant proportion of women with positive results for human papillomavirus deoxyribonucleic acid and normal cytologic findings had cervical intraepithelial neoplasia when cytologic rescreening was done.

The effect of trisomy 18 on transverse cerebellar diameter 72

Lyndon M. Hill, MD, Sandra Marchese, MS, Carol Peterson, RDMS, and Joanne Fries, RDMS
Pittsburgh, Pennsylvania

Measurement of the transverse cerebellar diameter or evaluation of the cisterna magna cannot replace a thorough anatomic survey in the detection of trisomy 18.

Porencephalic cyst: A complication of fetal intravascular transfusion 76

Gary A. Dildy III, MD, Leon G. Smith, Jr., MD, Kenneth J. Moise, Jr., MD, Lorraine E. Cano, RN, and Diane E. Hesketh, RN
Houston, Texas

Blood hyperviscosity and fetal bradycardia during intrauterine transfusion for Rh alloimmunization may have contributed to the development of a cerebral porencephalic cyst.

Hyporegenerative anemia associated with intrauterine transfusion in rhesus hemolytic disease 79

James A. Thorp, MD, Timothy O'Connor, MD, John Callenbach, MD, Gary R. Cohen, MD, John D. Yeast, MD, James Albin, MD, and Fred Plapp, MD, PhD
Kansas City, Missouri

Prolonged hyporegenerative anemia occurring in newborns after multiple intrauterine transfusions for rhesus hemolytic disease is associated with low erythropoietin levels and persistent antibody titers.

Daily administration of the progesterone antagonist RU 486 prevents implantation in the cycling guinea pig 82

Marcelo C. Batista, MD, Teresa L. Bristow, BA, Jeselle Mathews, MD, William S. Stokes, DVM, D. Lynn Loriaux, MD, PhD, and Lynnette K. Nieman, MD
Bethesda, Maryland

Daily administration of the antiprogestin RU 486 throughout the estrous cycle inhibits implantation in cycling guinea pigs and offers a novel strategy for human fertility control.

Fetal heart rate response to vibroacoustic stimulation during low and high heart rate variability episodes in late pregnancy 86

John A.D. Spencer, MB, BS, Anne Deans, MB, BS, Peter Nicolaidis, MD, and Sabaratnam Arulkumaran, MD
London, England

A transient tachycardia followed vibroacoustic stimulation in both low and high fetal heart rate variability, and subsequent variability remained high in all cases until the next behavioral cycle.

Elective versus emergency cesarean hysterectomy cases in a residency program setting: A reveiw of 129 cases from 1984 to 1988 91

Whitney Gonsoulin, MD, Rose T. Kennedy, MD, and Kathy H. Guidry, MD
New Orleans, Louisiana

One hundred twenty-nine cases of cesarean hysterectomy were reviewed to compare demographic and operative parameters and to establish the safety of elective hysterectomy at the time of cesarean section.

Transcervical endoscopic verification of congenital anomalies in the second trimester of pregnancy 95

Mark T. Cullen, MD, John Whetham, MD, Richard R. Viscarello, MD, E. Albert Reece, MD, Luis Sanchez-Ramos, MD, and John C. Hobbins, MD
Jacksonville, Florida, and New Haven, Connecticut

Transcervical endoscopy was useful in verifying prenatally diagnosed anomalies before pregnancy termination.

Trophoblast from anembryonic pregnancy has both a maternal and a paternal contribution to its genome 98

Deborah J. Henderson, BSc, Phillip R. Bennett, MD, Charles H. Rodeck, Gillian S. Gau, MD, Susan Blunt, MSc, and Gudrun E. Moore, PhD
London, England

Unlike complete hydatidiform mole and mouse androgenone development, which have only a paternal contribution to their genome, anembryonic pregnancy has genetic contributions from both parents.

Hydrops fetalis in the McKusick-Kaufman syndrome: A case report 102

Robin S. Rosen, MD, and Maureen E. Bocian, MD
Orange, California

This case report shows the importance of genetic-dysmorphologic evaluations in cases of nonimmune hydrops for counseling and future prenatal diagnosis options.

Contents

Correlation between sexual abuse and somatization in women with somatic and nonsomatic chronic pelvic pain 104

Robert C. Reiter, MD, Lisa R. Shakerin, MD, Joseph C. Gambone, DO, and Alison K. Milburn, PhD

Iowa City, Iowa, and Los Angeles, California

Somatization scores were found to correlate with history of sexual abuse in women with nonsomatic, but not somatic, chronic pelvic pain.

Cesarean section by local anesthesia in patients with familial dysautonomia 110

Joseph R. Leiberman, MD, Adolph Cohen, MD, Arnon Wiznitzer, MD, Channa Maayan, MD, and Lev Greemberg, MD

Beer Sheva, Jerusalem, Israel

Local anesthesia for cesarean section is a suitable alternative in patients with familial dysautonomia.

Tumor necrosis factor-α and interleukin-1β production by human fetal Kupffer cells 112

William H. Kutteh, MD, PhD, William E. Rainey, PhD, Bruce Beutler, MD, and Bruce R. Carr, MD

Dallas, Texas

Human fetal Kupffer cells have mature macrophage functions (phagocytosis, production of cytokines) early in gestation, which may have a significant impact on the development of the fetus.

Endothelin production by amnion and its regulation by cytokines 120

Murray D. Mitchell, DPhil, Sarah Lundin-Schiller, BA, and Samuel S. Edwin, BS

Salt Lake City, Utah

Human amnion cells produced significant amounts of endothelin 1 and 2, although the rate of biosynthesis was approximately one tenth that of human umbilical vein endothelial cells.

Uterine and fetal Doppler flow changes after intravaginal prostaglandin E_2 therapy for cervical ripening 125

William F. Rayburn, MD, Joseph C. Anderson, MD, Carl V. Smith, MD, and Lori L. Appel, RDMS

Omaha, Nebraska

Low doses of different prostaglandin E_2 preparations used for cervical ripening did not cause remarkable acute changes in the uterine and fetal Doppler flow velocities.

Does intensive glycemic control in diabetic pregnancies result in normalization of other metabolic fuels? 126

E. Albert Reece, MD, Donald R. Coustan, MD, Robert S. Sherwin, MD, Susan Tuck, MD, Sue Bates, RN, Theresa O'Connor, MPH, and William V. Tamborlane, MD

New Haven, Connecticut, and Providence, Rhode Island

Intensive glycemic control of insulin-dependent diabetes during pregnancy is associated with the normalization of other insulin-sensitive metabolic fuels.

(Contents continued on page 14A)

Contents continued from page 13A

The enhanced production of placental interleukin-1 during labor and intrauterine infection 131

Takeshi Taniguchi, MD, Noboru Matsuzaki, MD, PhD, Takashi Kameda, MD, DMSi, Kouichiro Shimoya, MD, Toushun Jo, MD, Fumitaka Saji, MD, DMSci, and Osamu Tanizawa, MD, DMSci
Osaka, Japan

Placental interleukin-1 production is enhanced during labor and chorioamnionitis.

Fibrinolytic parameters in normotensive pregnancy with intrauterine fetal growth retardation and in severe preeclampsia 138

Amparo Estellés, MD, PhD, Juan Gilabert, MD, PhD, Francisco España, PhD, Justo Aznar, MD, PhD, and Manuel Galbis, MD, PhD
Valencia, Spain

A decrease in type 2 plasminogen activator inhibitor was found in pregnancies with intrauterine growth retardation, and a significant correlation between type 2 plasminogen activator inhibitor levels and fetal weight was observed.

Arterial blood flow velocity waveforms of the pelvis and lower extremities in normal and growth-retarded fetuses 143

Giancarlo Mari, MD
Houston, Texas, and New Haven, Connecticut

The fetal femoral artery pulsatility index does not seem to be a good indicator of adverse fetal outcome; reverse diastolic flow is normal for the fetal femoral artery velocity waveforms.

The influence of contamination of culture medium with hepatitis B virus on the outcome of in vitro fertilization pregnancies 152

Helena C. van Os, MD, Aat C. Drogendijk, PhD, Willem P.F. Fetter, PhD, Rudolf A. Heijtink, PhD, and Gerard H. Zeilmaker, PhD
Rotterdam, The Netherlands

An acute clinical or subclinical hepatitis B infection during pregnancy appears to have no negative influence on pregnancy course or outcome.

Current Development

Early detection of preeclampsia 160

G.A. Dekker, MD, PhD, and Baha M. Sibai, MD
Amsterdam, The Netherlands, and Memphis, Tennessee

Clinical, biophysical, and biochemical tests that have been proposed to predict the development of preeclampsia are reviewed and their clinical usefulness is evaluated.

Contents

BASIC SCIENCE SECTION

Effects of maternally administered epidermal growth factor on placental permeability 173

Francis Mimouni, MD, Steven B. Hoath, MD, and Gail Hammond, BS

Cincinnati, Ohio

Maternally administered epidermal growth factor has a potent action to increase placental permeability.

Effect of clomiphene citrate treatment on endometrial estrogen and progesterone receptor induction in women 177

Marc A. Fritz, MD, Ronald T. Holmes, and Edward J. Keenan, PhD

Wright-Patterson Air Force Base, Ohio, and Portland, Oregon

Clomiphene citrate treatment (150 mg) did not affect concentrations of immunoassayable midcycle or late luteal phase endometrial estrogen and progesterone receptors in normal ovulatory women.

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep 185

Susan A. Arnold-Aldea, MD, Ron A. Auslender, MD, and Julian T. Parer, MD, PhD

San Francisco, California

Meclofenamate infusion did not cause any significant change in renal blood flow in the normoxic sheep fetus and it did not significantly alter the renal response to moderate or severe hypoxia.

Isolation and purification of microvascular endothelium from human decidual tissue in the late phase of pregnancy 191

Eileen D.M. Gallery, MD, Janet Rowe, BSc, Leslie Schrieber, MD, and Christopher J. Jackson, MAppSc

St. Leonards, New South Wales, Australia

A method for the isolation, purification, and culture of endothelial cells from human decidual tissue in the late phase of pregnancy is described, and their culture requirements are outlined.

Calcium every day
Aerobics every wee
Bone loss every yea

She needs PREMARIN to help prevent further bone loss

Calcium[1] and exercise are not enough to prevent postmenopausal osteoporosis, since estrogen deficiency is the primary cause.[2] PREMARIN is the only brand of estrogen indicated to prevent further bone loss and in a recently published study has been shown to reduce the risk of hip fractures by as much as 66%.[3]

Early PREMARIN therapy offers the best protection

The most significant rate of bone loss occurs in early menopause. PREMARIN can help maintain bone mass, preventing the progression of osteoporosis and its consequences.

Protection continues as long as estrogen therapy continues

Clinical studies show that within three years of menopause when therapy is withdrawn, bone loss begins again.[4]

PREMARIN®

(conjugated estrogens tablets)

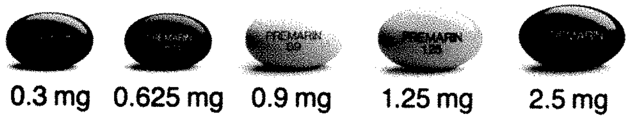
Proven benefits for menopause and beyond

Estrogens have been reported to increase the risk of endometrial carcinoma in postmenopausal women. Estrogens should not be used in women (or men) with any of the following conditions: known or suspected 1) pregnancy, 2) breast cancer, 3) estrogen-dependent neoplasia, 4) undiagnosed abnormal genital bleeding, 5) active thrombophlebitis or thromboembolic disorders.

See important information on adjacent page.

For moderate-to-severe vasomotor symptoms and for osteoporosis

PREMARIN®
(conjugated estrogens tablets)



The appearance of these tablets is a trademark of Wyeth-Ayerst Laboratories.

For atrophic vaginitis

PREMARIN®
(conjugated estrogens)

Vaginal
Cream
0.625 mg/g

BRIEF SUMMARY *(FOR FULL PRESCRIBING INFORMATION AND PATIENT INFORMATION, SEE PACKAGE CIRCULARS.)*

PREMARIN® Brand of conjugated estrogens tablets, USP
PREMARIN® Brand of conjugated estrogens Vaginal Cream, in a nonliquefying base

1. ESTROGENS HAVE BEEN REPORTED TO INCREASE THE RISK OF ENDOMETRIAL CARCINOMA.
Close clinical surveillance of all women taking estrogens is important. Adequate diagnostic measures including endometrial sampling when indicated should be undertaken to rule out malignancy in all cases of undiagnosed persistent or recurring abnormal vaginal bleeding. There is currently no evidence that "natural" estrogens are more or less hazardous than "synthetic" estrogens at equiestrogenic doses.
2. ESTROGENS SHOULD NOT BE USED DURING PREGNANCY.
Estrogen therapy during pregnancy is associated with an increased risk of congenital defects in the reproductive organs of the male and female fetus, an increased risk of vaginal adenosis, squamous-cell dysplasia of the uterine cervix, and vaginal cancer in the female later in life. The 1985 DES Task Force concluded that women who used DES during their pregnancies may subsequently experience an increased risk of breast cancer. However, a causal relationship is still unproven, and the observed level of risk is similar to that for a number of other breast cancer risk factors.

There is no indication for estrogen therapy during pregnancy. Estrogens are ineffective for the prevention or treatment of threatened or habitual abortion.

DESCRIPTION: PREMARIN (conjugated estrogens, USP) contains a mixture of estrogens, obtained exclusively from natural sources, blended to represent the average composition of material derived from pregnant mares' urine. It contains estrone, equilin, and 17α-dihydroequilin, together with smaller amounts of 17α-estradiol, equilenin, and 17α-dihydroequilenin as salts of their sulfate esters. Tablets are available in 0.3 mg, 0.625 mg, 0.9 mg, 1.25 mg, and 2.5 mg strengths of conjugated estrogens. Cream is available as 0.625 mg conjugated estrogens per gram.

INDICATIONS AND USAGE: Moderate-to-severe vasomotor symptoms associated with the menopause. (There is no evidence that estrogens are effective for nervous symptoms or depression which might occur during menopause and they should not be used to treat these conditions.) Prevention and management of osteoporosis (abnormally low bone mass). Atrophic vaginitis. Atrophic urethritis. Hypoestrogenism due to hypogonadism, castration or primary ovarian failure.

PREMARIN (conjugated estrogens) Vaginal Cream is indicated in the treatment of atrophic vaginitis and kraurosis vulvae.

PREMARIN HAS NOT BEEN SHOWN TO BE EFFECTIVE FOR ANY PURPOSE DURING PREGNANCY AND ITS USE MAY CAUSE SEVERE HARM TO THE FETUS (SEE BOXED WARNING).

CONTRAINDICATIONS: Estrogens should not be used in women (or men) with any of the following conditions: 1. Known or suspected pregnancy (see Boxed Warning). 2. Known or suspected cancer of the breast except in appropriately selected patients being treated for metastatic disease. 3. Known or suspected estrogen-dependent neoplasia. 4. Undiagnosed abnormal genital bleeding. 5. Active thrombophlebitis or thromboembolic disorders. 6. Estrogen replacement therapy has not been reported to increase the risk of thrombophlebitis and/or thromboembolic disease. However, there is insufficient information regarding women who have had previous thromboembolic disease.

PREMARIN Tablets and Vaginal Cream should not be used in patients hypersensitive to their ingredients.

WARNINGS: Some studies suggest a possible increased incidence of breast cancer in women taking higher doses of estrogen for prolonged time periods. The majority of studies have not shown an association with usual estrogen replacement doses. Endometrial cancer risk among estrogen users was about 4-fold or greater than in non-users, and appears dependent on treatment duration and estrogen dose. In patients on combined estrogen-progestin therapy, this risk appears to be decreased. (See PRECAUTIONS below.)

Estrogen therapy during pregnancy is associated with an increased risk of fetal congenital reproductive tract disorders.

A 2.5-fold increase in the risk of surgically confirmed gall bladder disease in women receiving postmenopausal estrogens has been reported.

Large doses of estrogen such as those used to treat prostate and breast cancer have been shown to increase the risk of non-fatal myocardial infarction, pulmonary embolism, and thrombophlebitis in men. This cannot necessarily be extrapolated to women. However, to avoid theoretical cardiovascular risk caused by high estrogen doses, the doses for estrogen replacement therapy should not exceed the recommended dose.

Blood pressure should be monitored with estrogen use, especially if high doses are used.

Estrogens may lead to severe hypercalcemia in patients with breast cancer and bone metastases.

PRECAUTIONS: The addition of a progestin for 7 or more days of a cycle of estrogen administration reportedly lowers the incidence of endometrial hyperplasia. Studies of endometrium suggest that 10 to 13 days of progestin are needed to provide maximal endometrial maturation and elimination of hyperplastic changes. Additional risk, such as adverse effects on carbohydrate and lipid metabolism, may be associated with the inclusion of progestin in estrogen replacement regimens. The choice of progestin and dosage may be important in minimizing these adverse effects.

Physical examination and a complete medical and family history should be taken prior to the initiation of any estrogen therapy with special reference to blood pressure, breasts, abdomen, and pelvic organs, and should include a Papanicolaou smear. As a general rule, estrogen should not be prescribed for longer than one year without another physical examination being performed. Conditions influenced by fluid retention, such as asthma, epilepsy, migraine, and cardiac or renal dysfunction, require careful observation. Certain patients may develop manifestations of excessive estrogenic stimulation, such as abnormal or excessive uterine bleeding and mastodynia. Pre-existing uterine leiomyomata may increase in size during estrogen use. Estrogens should be used with care in patients with impaired liver function, renal insufficiency, or metabolic bone diseases associated with hypercalcemia.

The following drug/laboratory test interactions have been reported, some only with estrogen-progestin combinations (oral contraceptives):

1. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.
2. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by T_4 levels determined by column or by radioimmunoassay. Free T_3 resin uptake is decreased, reflecting the elevated TBG; free T_4 concentration is unaltered.
3. Impaired glucose tolerance.
4. Reduced response to metyrapone test.
5. Reduced serum folate concentration.

MUTAGENESIS AND CARCINOGENESIS: Long-term, continuous administration of natural and synthetic estrogens in certain animal species increases the frequency of carcinomas of the breast, cervix, vagina, and liver.

PREGNANCY CATEGORY X: Estrogens should not be used during pregnancy. See **CONTRAINDICATIONS** and Boxed Warning.

NURSING MOTHERS: As a general principle, the administration of any drug to nursing mothers should be done only when clearly necessary since many drugs are excreted in human milk.

ADVERSE REACTIONS: The following have been reported with estrogenic therapy; changes in vaginal bleeding pattern and abnormal withdrawal bleeding or flow, breakthrough bleeding, spotting, increase in size of uterine fibromyomata, vaginal candidiasis, change in amount of cervical secretion; tenderness or enlargement of breasts; nausea, vomiting, abdominal cramps, bloating, cholestatic jaundice; chloasma or melasma that may persist when drug is discontinued, erythema multiforme, erythema nodosum, hemorrhagic eruption, loss of scalp hair, hirsutism; steepening of corneal curvature, intolerance to contact lenses; headache, migraine, dizziness, mental depression, chorea; increase or decrease in weight; reduced carbohydrate tolerance; aggravation of porphyria; edema; changes in libido.

ACUTE OVERDOSAGE: May cause nausea and vomiting.

DOSAGE AND ADMINISTRATION:

PREMARIN® Brand of conjugated estrogens tablets, USP

1. *Given cyclically for short-term use only.* For treatment of moderate-to-severe vasomotor symptoms, atrophic vaginitis, or atrophic urethritis associated with the menopause (0.3 mg to 1.25 mg or more daily). The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible. Administration should be cyclic (eg, three weeks on and one week off). Attempts to discontinue or taper medication should be made at three- to six-month intervals.
2. *Given cyclically:* Hypoestrogenism. Osteoporosis.

Hypoestrogenism due to: Female hypogonadism—2.5 mg to 7.5 mg daily in divided doses for 20 days followed by 10 day rest period. If bleeding does not occur by the end of this period, the same dosage schedule is repeated. Female castration or primary ovarian failure—1.25 mg daily, cyclically. Adjust upward or downward according to response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

Osteoporosis—0.625 mg daily. Administration should be cyclic (eg, three weeks on and one week off).

PREMARIN® Brand of conjugated estrogens Vaginal Cream

Given cyclically for short-term use only. For treatment of atrophic vaginitis or kraurosis vulvae.

The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible.

Attempts to discontinue or taper medication should be made at three- to six-month intervals.

Usual dosage range: 2 g to 4 g daily, intravaginally, depending on the severity of the condition.

Patients with an intact uterus who are treated with either PREMARIN Tablets or Vaginal Cream should be monitored for signs of endometrial cancer and appropriate measures taken to rule out malignancy in the event of persistent or recurring abnormal vaginal bleeding.

Revised August 21, 1989

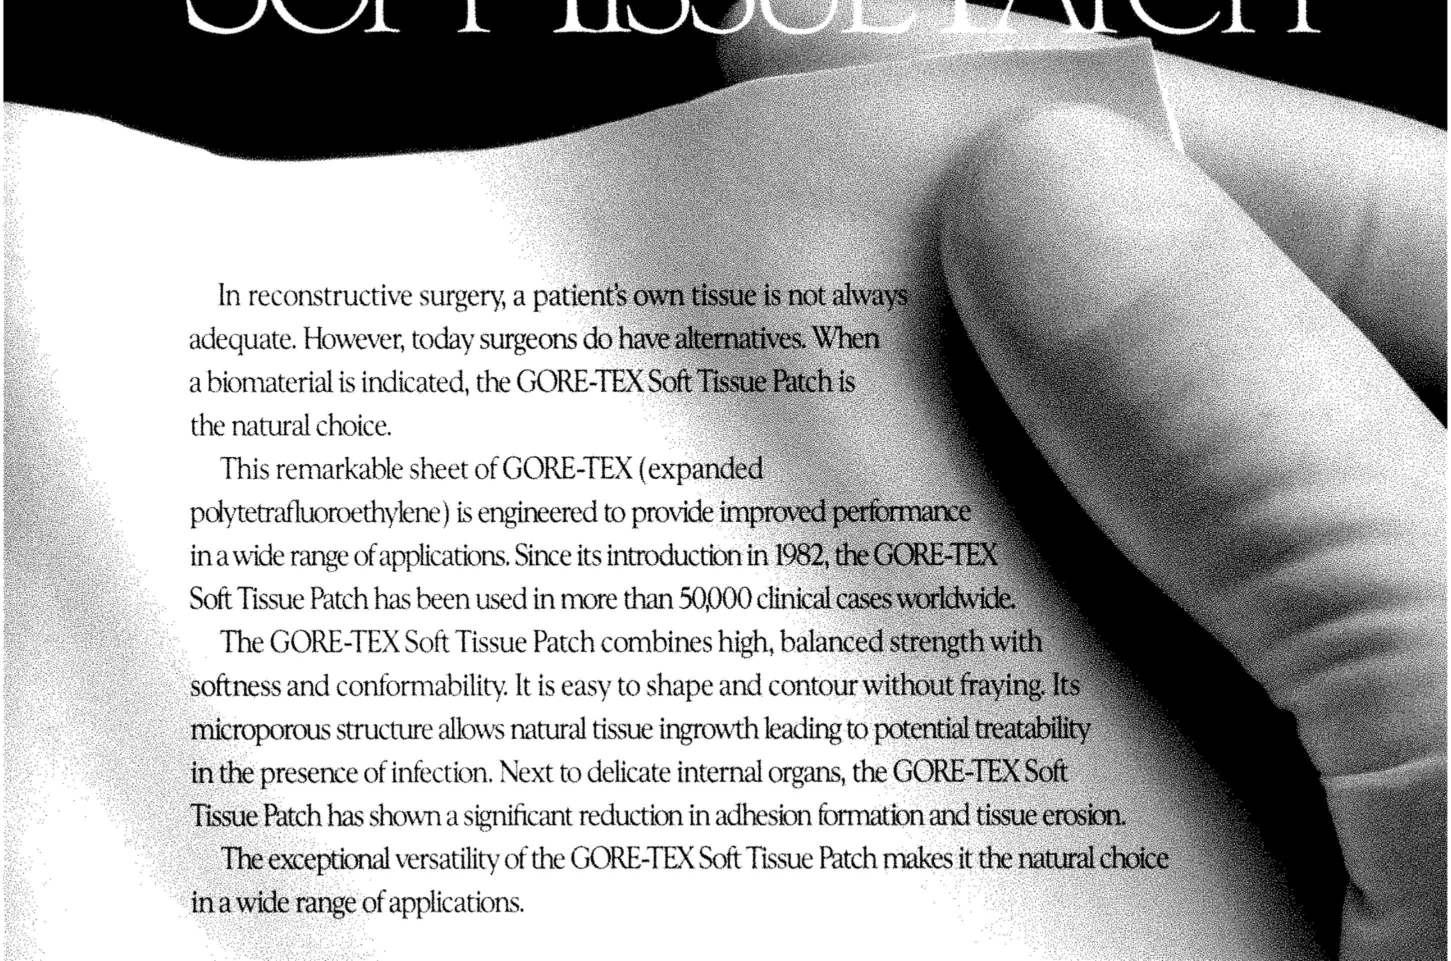
THE NATURAL CHOICE

GORE-TEX®
SOFT TISSUE PATCH



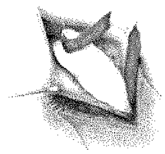
In reconstructive surgery, a patient's own tissue is not always adequate. However, today surgeons do have alternatives. When a biomaterial is indicated, the GORE-TEX Soft Tissue Patch is the natural choice.

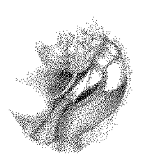
This remarkable sheet of GORE-TEX (expanded polytetrafluoroethylene) is engineered to provide improved performance in a wide range of applications. Since its introduction in 1982, the GORE-TEX Soft Tissue Patch has been used in more than 50,000 clinical cases worldwide.

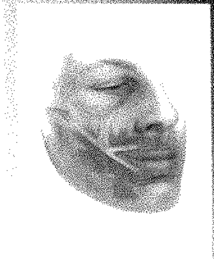
The GORE-TEX Soft Tissue Patch combines high, balanced strength with softness and conformability. It is easy to shape and contour without fraying. Its microporous structure allows natural tissue ingrowth leading to potential treatability in the presence of infection. Next to delicate internal organs, the GORE-TEX Soft Tissue Patch has shown a significant reduction in adhesion formation and tissue erosion.

The exceptional versatility of the GORE-TEX Soft Tissue Patch makes it the natural choice in a wide range of applications.

- Abdominal Wall Reconstruction
- Hernia Repair
- Thoracic Wall Reconstruction
- Diaphragm Reconstruction
- Rectal and Vaginal Suspension
- Urethral Suspension
- Gastric Banding
- Facial Augmentation and Sling Procedures
- Related Pediatric Reconstructions







☐ Please send further information on the GORE-TEX Soft Tissue Patch.
☐ Please arrange for a free clinical sample.
☐ Please have your sales representative call for an appointment.
